2. Building transistor matching network from S-parameters?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-01 11:56:53 UTC
From: jdc3538@ultb.isc.rit.edu
Message-ID: <1995Jan1.115653.1300@ultb.isc.rit.edu>
Source record: 114903

I'd like to match the output of a transistor to a 50 ohm load. The ARRL Handbook shows how to get there given the transistor's series equivalent resistance and capacitance. However, the Motorola data book lists "S" parameters for transistors. Are they one in the same?

I purchased Zverev's book during the summer, and just saw one in a bookstore this last month, so I'd be surprised to find it out of print.

You might call the following bookstores - I don't know if they'll ship, but it's worth the try: Staceys, and the Stanford University Bookstore (try both the campus and University Ave. locations for the Stanford store). I saw Zverev on one of their bookshelves. To get their numbers call information for the 415 area code - both stores are in Palo Alto, California.

My copy was $115, but it could be more now. But it's a beautiful book.

With regards to Terman - I just saw one yesterday, though couldn't tell you the edition (sometime in the 40's, I believe). Excellent condition and good price - but I already had one.

Now if I can just find a "Radiotron Designer's Handbook"!

Cheers,

- Jeff, WA6AHL

: ARRL Handbook shows how to get there given the transistor's series
: equivalent resistance and capacitance. However, the Motorola data
: book lists "S" parameters for transistors. Are they one in the same?

S parameters are the two-port parameters most often used to describe
2-ports above 100 mhz these days .... Since two ports are what we're
talking about, there are four params.
s11 : input reflection coefficient (magnitude and angle)
s12 : reverse transmission coefficient (magnitude and angle)
s21 : forward transmission coefficient (magnitude and angle)
s22 : output reflection coefficient (magnitude and angle)

in a good device, or two port amplifier network that is matched to 50
ohms (i.e. the two-port "box" is extended to include the transistor
and the matching network, whereas the s-parameters of the transistor
are the "unmatched" case):

the S11 value should be low since it represents the input return loss
the S12 should be low (this is the "reverse" amplification, or signal
travelling from output port to input port)
the S21 should be high (this is the "gain")
the S22 should be low, this is the output return loss, or match

Anyway.... S params are used because they are easy to measure at high
frequencies as compared to other two port parameters. Amplifier
design can easily become a scientific equation oriented design task
with s-params as far as the matching networks go.

On the other hand, for POWER transistors (i.e. anything that
is not being used in a truly class "A" mode {my best explanation}),
manufacturers usually do specify the input/output impedance at a given
frequency.

So, if you can get s parameters, you can obtain the necessary
information to determine the output impedance of a transistor
amplifier (as a whole two port network; the input network WILL affect
the output network if S12 is significant). ---OR--- you can use the
impedances given by the manufacturer to design your matching networks.

So NO, s params are not the same as the series equivalent impedance.

I'm building the FX440 FM transceiver, and so far I have no complaints. Oh, I was missing a 100 ohm 1/8 watt resistor and a .01 ceramic cap, but I might have lost those upon opening. Anyway, a trip to RS and about two dollars (I picked up some other parts to round out my parts box) and I fixed that. Yeah, I guess that I was disappointed a bit because of the missing parts, and suggest that Ramsey could do better. However, all of the important ICs, transisters and specialty parts were there, so I can cut them some slack.

I was interested in a radio that would support 9600bd for the TCP/IP network here. The TEKK 440mhz data rigs are cheaper, but I wanted a way to blow off some steam and get light-headed from solder (Heh). You don't build the TEKK either, which could be a blessing, depending. Anyhow, the price and some recent articles in Comm. Quarterly piqued my interest, and I purchased the FX440.

Here's my impression:
1. I found the instructions to be complete. Not as glossy as Heathkit (R.I.P.) but plenty good enough for a blurry-eyed, time-short, attention-deficit thirty-something computer network nerd to follow.
2. I appreciate the design of the unit. I learned something building it. I am thinking how I can kit-bash the thing for a data-only homebrew radio.
3. The components seem to be of good quality. The circuit board is thick and also of good quality.
4. Each stage has worked as promised.

Bottom Line:
I have had hours of enjoyment building this kit. I had NO feeling of remorse when I ordered and received the box in the mail. I have had no problems so far. I would purchase a similiar kit from Ramsey, and recommend the FX440 440Mhz kit.

12. Turn FM wirles mic into 2m rig?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-02 15:38:44 UTC
From: copeland@fohnix.metronet.com
Message-ID: <3e96m4$ebf@fohnix.metronet.com>
Source record: 114911

I picked up this Radio Shack FM wireless mic for $4 at a flea market
and was thinking about what could be done with it. It has a pot to adjust
from 88 to 108 mhz. Perhaps it could be changed into a *cheap* 2m rig?

Perhaps changing a component could make it tune 144-148 mhz?

Perhaps with a wire dipole tuned to this freq. and a higher voltage
battery this thing could hit a repeater?

Might have to add some kind of simple amplifier?

I've got a scanner for a receiver, a tech. liscense, but no radio yet.
(just passed test yesterday! also studying for morse code)

Anybody every tried something like this?

The problem with the wireless mic is that it uses a free running
modulated oscillator. I believe this kind of technique is not
legal on 2 meters. It would not be stable enough to stay on
any one frequency and really needs to be xtal controlled.

It would be more trouble to modify that mic than it would be to
build an appropriate 2m transmitter from scratch.

If you are looking for interesting conversion projects, I have been
successful in converting the better 49MHz HTs from Radio Shack to 6
meters. These units are xtal controlled, have rx squelch and work
quite nicely on 6 meters.

Zack is right about the MGF1302 being still one of the very best devices for 432MHz... but not for 144 (power GaAsFETs giver higher IP with acceptable NF) or for 1296 and up (low-cost HEMTs such as the FHX05 are better, and some good designs are becoming available). Not that you'd be able to tell much difference in the NF for any ham application except EME.

Moritz also has a good point about some of the older preamp designs being of very doubtful stability. The more we look into it, the more it seems that differences between performance on the bench and on the antenna may be caused by oscillations at some frequency totally unrelated to the band in use. A common scnario is that the preamp is still usable but you have an uneasy feeling that it's not working as well as it should...

These days I'm very reluctant to touch a preamp design that hasn't been extensively modeled AND THEN had several prototypes tested on a network analyser from DC to daylight, to establish their reserves of stability against component variations and unexpected input/output mismatches. I'm even willing to sacrifice some NF for that peace of mind.

If you're interested in thoroughly engineered preamp designs, I second Zack's recommendation to subscribe to the DUBUS quarterly.

I have to agree that a network analyzer is very useful if you
want to be careful. While programs such as Microwave Harmonica
and Touchstone are useful, they really aren't adequate for fully
determining the stability of preamps. They don't effectively
analyze waveguide effects that are often present with real designs.

How do you model that piece of conductive foam Ranier suggested
in his design?

Needless to say, ARRL Radio Designer *cannot* effectively
determine the stability of preamps using devices with high gain
out to 10 or 20 GHz. To do that you need sophisticated models
that aren't in this simulator.

On the other hand, a variable length of shorted transmission
line can be a cost effective toool for the amateur designer.
This might be as simple as a piece of coax with a lot of pinholes
in it.

20. cut-rate freq. counters

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-02 22:25:47 UTC
From: brucerob@blues.epas.utoronto.ca
Message-ID: <3e9uhc$aba@alpha.epas.utoronto.ca>
Source record: 114820

A local store is selling a freq. counter for $100 can., down from $250. I'm tempted even though it has all the markings of one of those Asian off-brands. The thing is good to 1.2 GHz, and in the HF band it is sensitive to <3 mV according to the manual. Question: is this sensitive enough to sniff out RF in homebrew circuits? The brand is 'Wisher' in case someone has some experience with the unit.

22. R-7100 freq/deviation meter add-on.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-03 01:32:36 UTC
From: andyw@cray.com
Message-ID: <1995Jan2.193236.5633@driftwood.cray.com>
Source record: 114823

While trying to set the deviation on a homemade 70cm FM transmitter, I wondered if anyone has built or bought a frequency error/deviation meter that could plug into the 10.7MHz IF output of (say) an Icom R-7100.

I seem to remember some ads showing spectrum analyser type displays as an add-on to radios with IF outputs.

If there are no existing plans or products, I wondered if I could get away with a just 10.7MHz FM discriminator, or whether I should throw a Moto IF chip at the problem. For freq error, I just want to measure the DC-bias out of the discriminator, and deviation is just the P-P output ? Calibration sounds like the usual nightmare..

Bill,
Try the ARRL handbook (old ones) they almost always had an
inverter or two in the "portable operation" section.

Ok. The transmitter chip is the MC2833. The appnote order number is MC2833/D. Follow it by a transistor tripler (I used some no number switching transistor from a grab bag) and PA brick (MHVxxx, I don't remember the exact number, scrounged it at Dayton, have to tear the thing apart and find the number. It's about 2.5 W out for 5mW in). A three section halfwave filter is on the output to suppress harmonics, standard Handbook circuit. The only cut and try in this whole project is the tripler. I guess I need to build another one of those using an identified part and give the coil tap information for matching the 50 ohm brick input. I just "uglied" it on a little blank piece of pc stock.

The receiver chip is the MC13135. The appnote order number is MC13135/D. Note, make sure you include the /, a MC13135D is a SO-24 packaged chip, not a data sheet. A preamp can help this chip, but isn't strictly necessary. I used an old ARR one, sans case, that had taken a lightning hit and been repaired but not reinstalled in my satellite setup (I'm using a SSB Electronics preamp there now). Add an output audio stage, either the old faithful LM386, or one using the MC34119. This latter chip has a mute input that's compatible with the receiver chip's squelch output.

Better, call Motorola and ask for the evaluation kits for the above chips. That gets you 2 each sample chips, the appnotes, and etched and drilled pc boards. The peripheral wiring to power, mic, speaker, etc should be self-explanatory (use RG174 for RF interconnect wiring). I used a surplus PIN diode switch module I picked up at a hamfest for TR switching the antenna, but any of the standard circuits, even a spare set of contacts on the PTT switch, will likely suffice.

I wired the modules together and tweaked it on the bench and then hot glued all the little postage stamp sized boards down in a small project box that was lying around, except for the PA brick which is clamped to the metal lid for heatsinking. No special shielding seemed to be required,

but I divided the Rx modules off from the Tx modules with a piece of scrap pc board just for luck. This thing won't win any beauty contests, but the spectrum analyzer says it's clean, and the Rx gives a 12 db SINAD of 0.2 uV. Once you've got all the pieces at hand, it's an afternoon project.

28. ARRL book: Intro to RF Design

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-03 17:44:25 UTC
From: derekn@vw.ece.cmu.edu
Message-ID: <DEREKN.95Jan3124426@vw.ece.cmu.edu>
Source record: 114828
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics

The January issue of QST has an ad for a new book, titled _Introduction to Radio Frequency Design_, by Wes Hayward. Before I plunk down my $30, I was wondering if anyone had taken a look at this book.

I've looked at a bunch of other books, but they all seem to fall into two categories:

1. All math and no practice - these don't provide any kind of intuitive explanation of how the circuits work, and they also don't give practical information (part numbers, etc.)

2. Cookbooks - these provide lots of real circuits, but don't really explain how they work. (The ARRL Handbook is the classic example of this category.)

I want something that balances math with practice. I understand the basics of impedance, transistors, etc., but I have no intutive feel for oscillators, mixers, and so on.

So... is this book any better than the others? Does anyone have recommendations for some other book?

Thanks.

-> Does anyone have any insight to the quality of the radio kits
->produced by Ramsey (sp?) Electronics?
-It is very nice to have any company that provides kits for the builder.
-Ever since Heathkit stopped making kits, its been a big vacumn for builders.
-Ramsey has a reputable name, a new modern factory, and the latest wave
-soldering machine.

I have built a few Ramsey kits, and I would recommend avoiding them. In my experience, the designs are poor, parts quality varies (I guess 4.7 uF non-polarized lytics were on surplus sale - yep, they can sometimes be used instead of 10 uF polarized ones), and tuning instructions are non-existant. Assembly instructions are pretty good, but if you are building a transmitter, make sure you put it on a spectrum analyzer before feeding an antenna. My 2M kit had spurs out of the band, and the TX came on before the PLL locked, so it swept. And the squelch *still* thumps...

Look into Ten-Tec's line of kits. They are very nice (but a few of them are still being designed - the 2M xcvr and the 9-band SW RX).

/mike

BTW, what does having a wave-soldering machine have to do with the quality of their kits?

You might also consider

Electronic Filter Design Handbook
(LC, Active & Digital Filters)
Williams & Taylor
McGraw-Hill, Second Edition, 1988

ISBN 0-07-070434-1

This text uses Zverev as a reference and probably is quite
a bit cheaper. Last time I checked, Zverev was running close to
$100 from a technical bookstore.

Williams & Taylor is a modern network theory text insofar as
the approach to filter design is concerned, and the inclusion of
active and digital filter sections adds to its usefulness as a design
handbook.

If you're after "quick and dirty" LC filter design try Chris
Bowick's book "RF Design" published by Howard W. Sams; it's the most
"bang for the buck" design book I've ever used.

sci.electronics used to have some of this, albeit not very frequently. I
gave up reading it when it got too noisy.

Sometimes the boatanchors mailing list discusses tube-type test equipment.
There was a substantial thread on old Tek tube scopes sometime back.

No, but in the same vein, remember the Amateur Scientist column in Scientific American magazine that described making MOSFETs in your kitchen oven? Sometime in the 70's, I think.

: Zack Lau KH6CP/1 2 way QRP WAS

No, Zack, your standards are not too high. Most of the off-the-shelf imported transceivers do not do all those 3 examples well enough. Ten Tec score well by having a useful frequency spotting arrangement, but the oriental manufacturers seem to totally neglect this area. Some commercially made rigs have poor keying envelopes, but much more common are radios that mutilate dash-dot ratios - often differently in MOX and QSK modes.

As far as bad netting goes, people normally blame themselves and others, rather than blaming radios that despite immense feature lists, omit a simple and important one. People seem to be surprisingly tolerant of lousy receivers, assuming conditions to be bad rather than suspecting the radio. You have to have really bad TX audio or bad clicks before anyone comments to you.

There have certainly been many bad designs published, and those constructors who can read a design well enough to assess it are capable of designing their own anyway. Constructors not yet experienced enough to be able to tell the good from the bad usually blame themselves for their lack of success, and are badly discouraged from trying again.

A good design isn't the lowest cost, the lowest component count, the simplest looking schematic; it's something harder to define - the least hassle ! It has to be designed to work allowing for device tolerances, the need for awkward adjustments or fancy test gear has to have been designed out in a deliberate and calculated way. There should be guidance on troubleshooting and adjustment. It should work with genuine safety margins by design. Conservative over-engineering doesn't prevent high performance. The parts will cost a fair bit more, but the

saving comes in test equipment needs and the proportion of projects that wind up in the bin without ever having worked.

Cheers
David

I have this book and it's excellent. Wes Hayward's forgotten
more about RF than I'll ever know.

Not a whole lot of math in the book. He tries to give the reader
an intuitive grasp of the subject. I thought the chapter on
oscillators was excellent.

>remember the exact number, scrounged it at Dayton, have to tear the
>thing apart and find the number. It's about 2.5 W out for 5mW in).

The tripler transistor, given the low output power requirement, could
easily be a 2N5179 to go from 50MHz to 150MHz.

I have to agree, for a simple, easy to build high-band transmitter,
the PA modules are neat. There are stories about inadequate heatsinking
causing them to fail due to thermal cycling induced stress cracks in the
solder joints, but this can be avoided by operating the part with good
heatsinking and/or at a proper duty cycle.

Actually, if you can get around to building a PLL synth, say with an
MC145170, you can directly generate the 150MHz signal using a J310 FET
in a VCO and a 2N5179 buffer, then the PA module. This is actually pretty
easy; you can generate the serial control data for the MC145170 using the
parallel port on a PC (that's what I do).

At the low power level, a PIN switch shouldn't be hard to rig, using a 1/4
wave lumped constant section (i.e., a T high pass filter with Xc=Xl=50ohms)
and a couple of PIN diodes (one to couple the PA to the antenna on transmit
and another to short the receiver end of the 1/4 wave section on transmit).

>Once you've got all the pieces at hand, it's an afternoon project.

This is true of many things; I've often scoured data books looking for
things that seem neat or might catch my interest. I'll do this a few times
until I've got a big enough wish list and enough spare cash to make the
minimum order ($50) at Hamilton/Halmark or Wyle. Despite grumblings by some
net.folks to the contrary, these companies have been happy to do business with
me on orders of less than $70. There's also Mouser and Digi-Key. The advantage
to people like Hamilton/Halmark is that they tend to stock an excellent selection
of "exoctica", i.e., stuff that I like to play with. You can also get good deals;
I bought 50 Motorola J310 FETs for $.34/ea from Hamilton/Halmark, where RF Parts
gets $1 each for them....

By stocking up myself on parts that seem of general utility and neat,
I've been able to make my limited hobby time quite rewarding. For example,
one weekend afternoon last month, I built a 6m PLL synthesizer, spent most
of the time dinking around with the VCO components to get the right tuning
range :-).

Like I've said before, the competent electronics hobbyist today has it better
than he/she ever has. Really!

It's definatly a Mini-Circuits product, but I can find no 'SC-90' in my current catalog. The only things close are filters, marked 'SCLF-##' and splitter/combiners, marked **SC-##, where ** = ZF, ZM or Z, among others. There are mixers numbered 'SCM-#', but no '90' numbers.

try calling Mini-Circuits, 1-718-934-4500. If they can't tell you what it is, you may as well toss it.

Another good source for this is old GM/Delco starter solenoids. I think they're wound with abt 20AWG wire. When you take them apart, the winding stays intact on a nice handy bobbin for you! Watch out though, I think the later ones were wound with AL wire.

Hi,
I haven't seen the ad, or obviously the book, but it does look interesting.
I have enjoyed Wes Haywards righting over the years, and I think I might get this book just because of that. I know he wrote some books for Prentice Hall, and when I wrote them last year, I think they were out of print. This title sounds familiar, so I wonder if it is a reprint of it. I am assuming that this is published by the ARRL.
Have you ever seen SOlid State Design for the Radio Amateur? It came out about 1977, from the ARRL and it is still listed in their catalaog. It was written by Hayward and Doug DeMaw. It is a collection of circuits, some projects (some of which were previously published, otthers new) and text about more advanced topics. It was an advance over the average ARRL book of the time, being based on information rather than circuit tidbits or construction projects. It is still a good book for the material it covers. It is only outdated because things have advanced since then, with so many people expecting all the bells and whistles that come with modern ham equipment.
I am assuming this book is similar, though not the same. If it is a reprint, maybe it is ten years old? It probably does still have information of value, knowing the things Hayward has written about in the past. But hopefully it would be updated, if it is a reprint. If it's new, then it probably is worthwhile. I would think than that it covers advanced topics, but in a fashion that the average technical minded ham could grasp. In other words, he writes well, in terms common to all, about things that aren't being talked about.
So I can't say much about the book, but I hope this background helps. I'm going to the newsstand later to check out the ad, because I am interested in this book. Thanks for telling me about it.

My guess is that it is a splitter/combiner (SC) with an upper frequency
limit of 90 MHz. By the connector types on the box I would have guessed
it was for splitting the outputs of a TVRO block converter for driving
two different receivers (two users sharing antenna/preamp on one satellite
but viewing different channels). However from the "90" it sounds more like
it is for splitting 70 MHz IF signals two ways.
There's a possibility that the 90 refers to 90 degrees and that it is
a branchline coupler centered at a higher frequency but the size of the
package would probably indicate against this.

If you can find suitable adapters you might hook it to your 2M HT on
receive only (or low power transmit if you are daring) and see if you
hear signals slightly attenuated. If it is a ~90 MHz splitter, it will
probably still work reasonable at 144 MHz. If that works, you could
probably use it to drive a pair of suitably positioned 2M antennas
either for additional gain in a single direction or to tailor your
coverage area with two main beams of the same or different polarization.

Or you could offer it for sale on rec.radio.amateur.swap as a "surprise".

RI>: Does this mean that a new ham can start operating without a license in
>: hand as long as he has the C.S.C.E and knows his call?

RI>Of course not. You have to have a signed original in possession.

Actually, it DOES! As of December 20, 1994, applicants may now CALL the
FCC (1-800-322-11117), given a appropriate processing wait (maybe two
weeks or so) and if the license has been issued, the FCC will give the
applicant his/her new call and he/she may start operating IMMEDIATELY,
without having a hardcopy of the license. The theory now being that the
FCC already has what they need (the callsign of the operator, and the
record of the issuance), and that's all they need.

From: starin@netcom.com
Message-ID: <starinD1wwvu.lq4@netcom.com>
Source record: 114857

I need some good old fashioned advise from the gurus in this group who know a little about surface mount technology.

I have an elecronic device which is comprised of mostly surface mount components. Assuming I can figure out what each component is, can I then rebuild this device using standard components? What are the considerations? When I reverse engineer this device, can I say, substitute a 1/4 watt resistor for the surface mount 1/8 watt resistor, etc.

Any help would be greatly appreciated.

Thanks

This is the kind of thing I would love to have. If anyone has *any* pointers to this article, I'd sure appreciate it. I expect this was in the excellent "amateur scientist" column. I damn near built that copper vapor laser...

Steve

P.S. I'm serious here, I want to build my own MOSFET just to prove I can do it. I've got a buddy building a turbojet for the same reason.

> and Touchstone are useful, they really aren't adequate for fully
> determining the stability of preamps.

True - Rainer made that mistake when trying to model a Norton
feedback amplifier as a 2nd stage for 432. He couldn't model the
parasitic Ls and Cs in the transformer; instead of being
unconditionally stable as Microwave Harmonica predicted, it was
a FB power oscillator.

> They don't effectively
> analyze waveguide effects that are often present with real designs.

DUBUS has just arrived with an interesting article by WA8NLC
on real-life effects in microwave construction. (You've probably
seen it already.)

>
> How do you model that piece of conductive foam Ranier suggested
> in his design?

You don't. In the end you can only test the real thing.

> On the other hand, a variable length of shorted transmission
> line can be a cost effective toool for the amateur designer.

You can use it with a microwave power meter on the other
port. If leaving the other port unterminated, monitor the
DC operating condx with a 4.5 digit DVM.

> This might be as simple as a piece of coax with a lot of pinholes

Check my signature line to see if you want to consider me biased, but I can
say without reservation that this book is indeed worthwhile for those
interested in doing RF engineering, amateur or otherwise.

Wes's preface to the ARRL edition (the original Prentice-Hall printings are
now entirely out of print) notes that "this new printing has changed little
from the original...the major difference...is the inclusion of a disk
containing a collection of computer programs related to and derived from the
text." The added software aside, is it bad that the book hasn't been
"updated"? No, because, aside from fixing a glitch here or there (the sort
that inevitably creep in through the publication process), it didn't *need*
updating because it is component-nonspecific and still speaks well to its
intended audience. It ain't broke, so--somewhat like the Zverev filter book
others on the net rightfully cite as well worth tracking down because it
hasn't aged, or the Terman and Henney books many of us covet because of
their solid fundamentals--it didn't need "fixing."

If you have an interest in receiving real-time images from satelites
read on......

Equipment to receive these real-time images are manufactured in Queensland
Australia. This project began life as a research / recreational hobby by
a team of radio enthusists. The final outcome of the project was a system
to receive real-time images from polar orbiting weather satlites.

Images are available from American (NOAA), Russian (METEOR) and Chinese
(FENG-YUN) satelites as they traverse your geographical area. The
satelites transmit both visible light and infra-red images. Resolutions
vary from 2.4Kms to 5Kms per pixel.

The system comprises a simple omni-directional antenna, a suitable radio
receiver, demodulator card (AD converter) and viewing software suitable
for the viewing and manipulating images on IBM PCs.

An overall system price is in the order of $650 (Aust) with the possible
addition of a mast head pre-amp for $30. Various antenna equipment and
cabling is required and can be purchased for around $15. Detailed
diagrams are included for the construction of the antenna.

Please respond in e-mail if you are interested in obtaining more
information. Parts of the system are also available in kit form.

|> {New York}

Well Jeffrey, I don't know if I qualify as "knowledgable", but
that never stopped me before. :-)

There are just a few unanswered questions in your post.

1. How complex? I assume that you want a simple transmitter.
2. What mode? I assume that you want a CW transmitter, again due to
simplicity.
3. What frequency? I assume HF.
4. How much power output? I assume QRP levels.
5. How much money do you want to spend? I assume very little or you
want the joy and pride of building your very own.

Look in any of the ARRL handbooks. There are usually more than one.
I pulled the 1992 Handbook off the shelf here at the office and low
and behold, in chapter 11, page 11-2 there is a two transistor
simple, solid-state CW transmitter controlled by one crystal.
It's for 80M and probably less than 1/2 W output.

With current techniques, it's just about as cheap and with good
stability to go ahead and go with a VFO, thus allowing one to shift
frequency a little more to get away from QRM and ongoing QSOs in
progress.

You don't list your call in your post, so I don't know what your
experience level is or you license class, but I do hope that this
helps. If you've never built before, I recommend Chapter 25 of
the new 1995 Handbook on construction techniques. :-) :-)

There are number of other ARRL books around also that will help.
Email direct if you need more and good luck.

: 2. Cookbooks - these provide lots of real circuits, but don't really
: explain how they work. (The ARRL Handbook is the classic example of
: this category.)

Comment noted, understood, and agreed with !

***** AND ACTED UPON ! *****

I too felt that the handbook was weak on explanation, and threw a lot
of circuits at the reader without any real guidance on how to choose
between them. Amateur radio was my hobby as a kid, and formed the
foundation of my career. Faced with the opportunity to write a chapter
as part of the grand re-write for the 1995 edition, I felt it was my
chance to put back some of what I'd got from the hobby. OK, that may
sound trite, but it's nice to think you've done something worthwhile.

Writing the oscillators and synthesisers chapter was fun, but took up
most of my "spare" time for most of a year. Several friends helped by
reading attempts at difficult parts and then telling me what they *really*
thought of them. I've done my best to convey understanding, to paint a
moving picture of a functioning oscillator in a readers mind, to explain
the fundamental principle common to all oscillators, to explain the
inextricable involvement of noise etc etc. I've tried to show how
reliable, robust, synthesisers are designed, and I've unravelled the
synth of a good HF rig to show how it works, what compromises its
designers took and what could be done to improve on it.

I've done my best, I hope it's good enough. The feeling of it now
being irretrievably set loose and in the hands of those who will judge
it is strange. I feel quite nervous.

A copy of the final book has only recently arrived (does mail swim
across the Atlantic?), and I've enjoyed reading the other sections. The
whole tone of the book has changed. I think it is now far better at
explaining things.

: I want something that balances math with practice. I understand the
: basics of impedance, transistors, etc., but I have no intutive feel
: for oscillators, mixers, and so on.
: So... is this book any better than the others? Does anyone have
: recommendations for some other book?

Wes Heyward has plenty of experience and can write with authority on
practical matters, his intuitive understanding and maths are equally

good. I've learned a lot from what he's written. I wholeheartedly recommend everything he's written. I'd recommend reading carefully, and more than once. Even in the older "Solid state design for radio amateurs" there are some subtle gems that are only spotted later.

My opinion of the 1995 ARRL handbook will be biassed because of my involvement, and it would be most improper for me to recommend it :-). However, it is greatly changed. Lots of people have put in lots of work.

Please take a look at a copy, and judge for yourself.

I don't think there is any one "best" book. I think you'll find reading a few will give different views and explanations that are complementary rather than competitive. Sometimes I find that something in book "B" clicks in my mind, and I suddenly understand things better in books "A" and "C".

Cheers
David GM4ZNX

In the 50s, I can remember hearing about people who made their own
point-contact transistors, just like Bardeen et al did.

>-*-

>/|\ ardai@maven.dnet.teradyne.com n1ist@netcom.com

The wave soldering machine refers to subassemblies in newer kits to come.

Remember, you only get what you pay for in this world, and you don't pay
a lot for Ramsey Kits.

Every one of the Ramsey kits are usable, some need more technical
kowledge than end assemblers can muster up. At least Ramsey is willing
to make it work for the buyer, if the buyer can't do it himself.

73. Active SMD mixer available for 1-1000Mhz?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-05 23:47:21 UTC
From: snorris@harp.aix.calpoly.edu
Message-ID: <1995Jan05.234721.153766@zeus.aix.calpoly.edu>
Source record: 114772

I'm working on a project that requires a mixer with ~1-1000Mhz RF, 400Mhz LO, and up to 500MHz IF. I would also like it to be able to use a low LO drive (down to around about -10dBm) and have a LNA as well. All preferably in an 8 pin SOIC with supply voltage of 5V.

Any recommendations? I've looked around quite a bit, but have not yet found one with the frequency ranges that I need. Presently I have a passive mixer in the design that has the ranges I need, but would like to explore the possibility of using and active device to possibly shrink the size and get a little better sensitivity without having to add discrete amplifiers.

Any help and/or advice here would be appreciated

thanks,

Sean

)--
)Jeffrey
){New York}

First a real nit-pick: either use "is composed of" or "comprises".

Now to really answer your question.

So long as (at the frequencies used) the components used are "really"
there as discrete components (as opposed to including "stray" or
"parasitic" effects of layout etc.) what you propose to do should work.
Do not try to re-do a stripline circuit, though. Even at 100 MHz layout
is often as important than component values.

Mike

^^^^^^^^^^^^^^^^^

Oops! I originally worded that as "more important than", but then
thought a little bit, and decided that at 100 MHz it should be "as
important as". Unfortunately one the first part got changed.

Sorry for any confusion.

81. Power control of Class C amplifier

Newsgroup: rec.radio.amateur.homebrew

>transmissions, so the drive power is reduced same as it would be
>for voice transmission.

Tom:

Class C amplifiers are used for FM, typically at VHF and above. I've been using mobile radio PA's for some time as cheap amplifiers for HT's, both VHF and UHF and as repeater TX. The voltage supplying a stage in the PA is controlled by a series pass regulator circuit feeding the PA, with feedback from a "power adjust" pot, a level control ciruit, temperature and reflected power sensors. In small HT transmitters, the "controlled stage" can be milliwatts and class A.

Usually the "controlled stage" is the predriver, the first transistor on the PA board, handling a few watts (5 watts typ). This has the advantage of controlling smaller currents than what you would find thru the final PA transistors. For instance, a 110W PA will consume 20+ amps in the final PA transistors.... current which you don't want to regulate.

There are a wealth of older radios, from GE, Motorola, etc that are great for amateur repeater PA's or HT amplifiers, and cheaply available (if not even free). Some suggestions are Mitrek, Micor, Pulsar (this one is the best! It is an old IMTS radio with removable PA, complete with it's own power control board, isolator and dummy load.... on UHF, -10 dBm in gets you +47 dBm out.... add a fan and you are fine for continuous duty). Look for a self contained PA that can easily be separated from the main assembly. This is assuming you want to go this route instead of building from scratch.

For situations that don't demand power regulation, just tie the controlled stage to max volts required for full output. If possible, try to extracate the control circuitry though; it makes life easier. Your mileage may vary.

Hope this helps. To all nethams... this is a good newsgroup with actual technical content, unlike the ham-equipment newsgroup (primarily concerned with out-of-band mods). Good show!

Tony, VE3PEP
ai797@freenet.toronto.on.ca

PS. Why pay for NEW when USED will do!!! Any other repeater hackers out there? Solar powered repeaters a specialty.

84. ROANOKE DF PWBs available

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-06 17:17:13 UTC
From: P06288@email.mot.com
Message-ID: <1995Jan6.171713.5441@schbbs.mot.com>
Source record: 114784

I apologize in advance if this is the wrong place for this posting. If it belongs elsewhere please let me know.

Several weeks ago I placed a posting looking for ROANOKE DF PWB kits. A number of people wanted me to post a source if I located one. I found an ad in 73 Mag for some and here is the following information:

AB5CK, Tom Lewis has Roanoke doppler boards available for assembly. They are a single board with the 16 LED display and are high grade PWBS with solder mask and silk screen for component locations. He says they have LOTS of bypass caps for lowered noise. They also have an improved audio amp. Cost is $49.95 including shipping etc. Check or MO will work but he holds boards until ck/MO clears. Cashiers check is preferred and gets immediate shipment. His number is (817) 428-8200. Address is 6721 Rolling Hills Dr., N. Richland Hills, TX 76180.

I am not affiliated with him in any way and cannot answer any questions or provide any help. Please contact him directly at the above.

85. Kenwood Computer/Transceiver Kit For Sale

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-06 18:23:58 UTC
From: cwtech@infinet.com
Message-ID: <3ek1ru$lk4@rigel.infinet.com>
Source record: 114785
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.homebrew

I have a partially assembled transceiver/computer interface kit for Kenwood rigs I will sell for $25.

Explanation: I sell these kits based on my 2/93 QST article ("Everything You Always Wanted to Know About Computer Controlling Modern Radios"). They are also detailed in chapter 22 of the 1995 Handbook. Anyway, I designed a new circuit board for the Kenwood models and built an interface with it to the point that I could statically test it. It works and I incorporated the new PCB in the kits.

Having no Kenwood radios, I don't really have a use for the interface board and I wouldn't think of disassembling it for kit parts. Soooo, if anybody wants a cheap way to get a nice interface, buy this board and put it in a case, add the cables (provided) and you're ready to go. I usually sell these kits for $49, so this is a pretty good deal.

I also still sell the kits for both Icom/Ten-Tec/Yaesu $47. E-mail if you're interested. Thanks.

86. GaAsFET preamp retuning

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-06 20:42:36 UTC
From: spbachhu@mtu.edu
Message-ID: <3ek9vs$aah@maxwell9.ee>
Source record: 114790

In the ARRL Handbook there are a couple of designs for 144 Mhz GaAsFET preamps. I was wondering what it would take to retune one of these for the FM broadcast band. I know it would probably only take changing a couple capacitors or inductors, but I am unfamiliar with input matching networks, and don't know what values to use.

Otherwise, we could bypass this whole discussion if someone knows of an existing preamp (either commercially available or in kit form) with a noise figure under 1 decibal.

any help appreciated.

Steve Bachhuber
spbachhu@mtu.edu

Steve,
Why 1 dB? Have you measured the background noise level at
your site with your antenna system? Depends where you are... but... I
dunno... after doing some research recently (based on a hunch), I
found that Noise levels due to humans and "galactic" sources are very
significant below 200 mhz.

(those curious about this, check out the noise chapter (29 in my
edition) of "Reference Data for Radio Engineers", ITT/ Sams.) I don't
trust the data given in this chapter as being "absolute", but it
supports my experiences.

In other words, I am not sure that you will gain much with a
noise figure lower than 1 dB over something with a noise figure of 3-6
dB (as a cheap alternative).

One could come up with a circuit costing less than $5 or so if
you used relatively common parts like the 2n5179 (NPN), 2n5109(NPN),
MPF-102/2n4416 (N-JFET). *OR* a bandpass filter and a MMIC.

Any comments from the Noise Figure gurus? Zack?

just my $0.02

-Lance

p.s. after a little discussion, I would be happy to try to help you
out... this is a topic of interest to me.

Such interim operating permits have been used in the commercial industry
for several years with great success. As soon as the coordinator picks the
freqs and sends the stuff to the FCC, as callsign is issued by the
computer and the happy new licensee can start operating immediately,
without the hard copy of the license.

Yep, they're called panadaptors. Useful little buggers at times, but
a wideband spectrum analyser is better if you want to catch harmonics
and far out spurs.

>If there are no existing plans or products, I wondered if I could
>get away with a just 10.7MHz FM discriminator, or whether I should
>throw a Moto IF chip at the problem. For freq error, I just
>want to measure the DC-bias out of the discriminator, and deviation
>is just the P-P output ? Calibration sounds like the usual nightmare..

Yep. A DC coupled scope on the discriminator output of your receiver
will do for frequency error and deviation measurements. You just have
to calibrate it with a known signal source. Crude deviation measurements
can be done with just a VU meter plugged into the headphone jack of
a receiver. The meter will only be RMS, but that's good enough for many
uses, or you can build a peak hold circuit for it. Feed in a 1 kHz modulated
signal of known deviation, set the volume control for 0 VU and then use the
receiver to measure other signals. A minus 3 db reading would indicate half
the deviation of the known standard, a plus 3 db reading would indicate
twice the deviation of the standard. Of course you could calibrate the meter
directly for several modulating frequencies and deviations. Because of
de-emphasis in the audio chain, the response will be non-linear with
modulating frequency, so you have to use the same modulating frequency
for the standard and the unknown to get useful results.

If you build your own deviation meter using the MC13135, you can also
get a reliable indication of signal strength from the RSSI pin. It has
a guaranteed log output over a wide range of signal levels. This can
be a good little project. You can use a pair of meters, one zero center
reading, and have signal strength, deviation, and frequency error readings
available to you. Put a SBL-1 in front of it, and a crystal LO or a
calibrated signal generator as a LO, and you have a complete measuring
instrument.

Or, you can do as I am doing and modify a scanner with the appropriate
receiver IC. My Uniden BC 760xlt uses a chip with RSSI and, of course,
discriminator output. With an external metering box, I have a wide range
communications monitor of relatively useful characteristics, and it's

still a scanner for the times when I don't need a test instrument.
Bring out the LO through a buffer stage, remember it's 10.7 MHz offset
from the display, and you have a signal generator tunable in 5 kHz
steps. With suitable step attenuators, you've got a nice addition to
the test bench.

> The January issue of QST has an ad for a new book, titled
> _Introduction to Radio Frequency Design_, by Wes Hayward. Before I
> plunk down my $30, I was wondering if anyone had taken a look at this
> book.

Yes, it's been around for a while under the Prentice-Hall imprint.
If you enjoyed 'Solid State Design' and are looking for more
information about the fundamentals, you'll learn a lot from 'IRFD'.

It isn't intended for radio hams - it's a professional text and there
are no constructional projects. Remember, the author is W A Hayward of
Tektronix, Inc writing for professionals, not good ole W7ZOI bringing
his professional expertise down to our level. But they're both the same
person, and this book is just as well-planned and clearly written as
you'd expect.

Here's the chapter outline (total of 372 pages plus index):

1. Low frequency transistor models
2. Filter basics
3. Coupled resonator filters
4. Transmission lines
5. Two-port networks
6. Practical amplifiers and mixers
7. Oscillators and frequency synthesizers
8. The receiver: an RF system

Chapters 1-5 are the fundamentals, which are applied in chapters 6-8.
There's some math, but only where it helps to make something clearer.

As one of the key books that link theory to real-life circuit design,
'Introduction to Radio Frequency Design' is right up there with
'The Art of Electronics' by Horowitz and Hill (need we add that Prof.
Paul Horowitz is a ham too?).

For me, 'IRFD' was the book that put the capital D into 'Design'. It
taught me the value of planning any RF project and doing a few very simple
calculations to show whether it has a chance of working properly,
instead of just switching on the soldering iron and grabbing the first
components that come to hand.

The price of the Prentice-Hall hardback in Britain was far out of
reach of amateurs. Last time I saw the British Library's inter-library
loan copy, it was completely broken-backed from repeated photocopying!
Now that it's available at a reasonable price, I'm certainly ordering

my own copy from ARRL.

Strongly recommended!

Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew

Just curious if there is any work going on with generating quadrature modulation from a PC sound card (such as the DSP16 / AD2100 based cards) ??

Seems like you could have some fun with one of these single chip quadrature modulators such as RF Micro-Devices RF2703 and then using the stereo output of the sound card (L+R), drive the I+Q inputs of the modulator... software on the DSP then decides if you are doing SSB, FM, FSK, etc...

You'd then put your analog signal to be transmitted input one of the sound card's input channels (L or R)...

Of course, the whole thing might be reversable, so that demod could be done as well.

Inquiring minds want to know...

Ne> to the 2AT or do I have to reduce it to 7.2v????

Ne> Don N6FNL <teixeira@ccnet.com>

Don: Build a regulator and don't run the IC-2AT any higher then 10 VDC.
I just opened an old adaptor I made for my IC-2AT years ago. I used
a 7808 regulator and placed a couple of IN4001 diodes in series with the
center lead of the 7808 to raise the regulator above ground.
Each diode increases the 7808 regulator's output voltage by about
0.7 volts, so experiment with the number of diodes- I used three-
until you get close to 10 VDC output.
I used electrolytics from the junk box and left the LED and the input
voltage jack in place in the old battery pack.
I've carried the homebrew battery eliminator and a cigarette lighter
plug and cable in the trunk of several cars. Just now tried plugging it
into my new '95 VW and the darn plug doesn't fit. Too small. Glad
I read your message. Got to replace that plug.
BTW, the IC-2AT is a real classic, bulletproof, and never left me
down. It's one of the few pieces of gear I won't trade.

102. Narrow IF filter question

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-07 22:58:51 UTC
From: starin@netcom.com
Message-ID: <starinD22564.3vI@netcom.com>
Source record: 114802

I have a Narrow IF filter designated as CFWS455HT, which I received from Murata electronics. I have a schematic which uses this part to help in reducing adjacent channel interference in my pro-2006 reciever. Problem is, the part which Murata sent me has different pin-outs thann the one in the schematic, although I've been assured it is the right part. Does anyone know the pin-outs on this IF filter? It has one leg on one corner, then four other legs running along the opposite side. I need to know which one is the "in", the "out", and the "common".

Any help much appreciated, or I will resort to calling Murata, which I prefer not to do, since this part was gratis.

Thanks

Source record: 114805

Try the following pinout. It's for a CFW455HT, but I'll bet it's
the same for your CFWS455HT. Can't find CFWS in any Murata catalogs.

The CFW is 11.0mm long, 7.0mm wide, and 8.5mm tall (excluding pins).
The CFW has Fo=455kHz, 6dB BW at +/-3kHz, Z=2k ohm, 6dB loss, 50VDC max.

```
|-----------------------|
| 4 3 2 1 | Bottom view of CFW's pins.
| |
| 5 | 1=input, 5=output, 2,3,4=ground.
|-----------------------|
```

Be sure your circuit matches your filter's input/output impedance.

Good luck with your modification.

I agree completely. My 4AT and 2AT are the only two handheld that don't go through batteries like a hot knife through butter! I am having trouble with my 2AT however. When +dup is set, the freq only raises 585 kHz instead of the full 600 kHz. I have not had that much time to look at it yet. Any ideas before I open her up?

I'm looking for older (cheaper, that is-hee hee) test equipment.
-20-30 MHz scope with modules (if any) and probes (Tek545, etc..)
-50-150 MHz frequency counter (old HP, etc..)
-Signal generator (0-300MHz or so), anything that works and has an accurate frequency readout.

If you have any stuff like this, please e-mail back. I'd pay cash or swap for ham gear (see previous post).

This would be cool, but I think you need DC output levels, and the soundblaster
outputs are AC-coupled.

Of course, you could add a couple of cheap DAC chips to the board with the
modulator...

I saw in a QEX article (I think) a block diagram of a DDS chip that had
DIGITAL I+Q inputs. This would give you a 1-chip SSB exciter!
You could probably hook it up to the parallel port. and just
use the soundblaster for the ADC.

My memory is hazy here, but I remember that Scientific American had a
book of projects and I believe one them dealt with listening to what
was referred to as the "dawn chorus" and "whistlers" caused by lightning.
The receiver was nothing more than an audio amplifier with a wire antenna
connected to it's input.

Try the 3sk124, 3sk205 Dual Gate GaAsFETs. They are under
$2 each
in small quantities from the local rep up here near
Chicago.

I get 24dB Gain, .55dB Noise figure on two with a simple
circuit (very stable)
and the 3sk205 models out to be around .5dB, 26dB gain and a
few dB higher on
3rd OIP.

If anyone is interested I'll dig up the name of the local
rep & phone number.

Superior to what though? 3 dB, 6 dB.... by what measure?

Well, it does depend on where you are and what you're doing.
however As we all know, technical specifications are often used as a
marketing ploy, rather than a practical advantage over a competing
product. I am not saying that you're wrong....

Here is an example similar to one that I'm using in the writeup of a
6m transverter I designed. (note that I'm using a higher frequency
band than broadcast...and this should by all indications be a more
conservative example).

#here we go:

hypothetical situation: 144 mhz receiver, 500 Hz bandwidth (like cw or somthing) and a
arbitrary Noise Figure (NF)

the MDS can be calculated as follows (power)
(this is in a 50 ohm resistor... i.e. kTB = noise power in dummy load)

P_MDS(dBw)= 10 x log (k * T * B) + Noise Figure

** k= boltzman's constant (1.38 x 10 ^ -23 joules/deg-Kelvin)
**
** T= the reference temperature (here we use 290 degrees Kelvin)
**
** B=bandwidth

= -177 dBw + NF

Or, converting to dBm, the result is

P_MDS(dBm)= -147 + NF

Now let's assume that the noise figure is 3 dB, then, theoretically,
we should be able to barely detect a signal at -144 dBm.

Not that this is a general rule, or "fact", but some studies done in
the fifties showed noise levels in urban, suburban, and rural settings.

In rural settings, the galactic background noise dominated, whereas
man-made noise dominated in the other two settings.

The data were shown in chapter 29 of "Reference data for radio engineers" (ITT/Sams). The graph provided showed background power levels referenced to kT (so no-matter the bandwidth, you could compare this level to you're receiver's noise temp/figure).

Anyway... at 144 MHz, from my estimation, the background noise power was

-143 dBm due to galactic (yes, would be a good idea to have a low noise figure).

-126 dBm due to suburban man-made noise (mega preamp not as critical, since the signal is nearly 20 dB of noise (hence the preamp contributes little)).

-112 dBm due to urban man-made noise. (pretty hefty amount of excess noise)

Hence, I propose that in many cases, "sensitivity" on the bench does not equal the "sensitivity" on the air.

Now, presumably, I would expect the noise levels would rise a few dB by lowering the frequency.

All I'm saying is that this *could* be the case. If you can get the cheapie mos/gaas fets, then go for it. My only point is that these findings were somewhat surprising to me, but they help to explain why many commercial equipment manufacturers don't worry about the last dB of noise figure improvement. (lots of two-way stuff has NF's above 6 dB).

: Many GaAsFETs only cost $10-15.

Hey, that's a lot of beer for this college student. I like to find reasons for using cheap devices, more than just because I can afford them. :)

Anyway... didn't mean to start a whole controversy... just want to hear what other people have to say. Presumably Steve either

Johan, KC7WW, who has written some articles for QEX on the Cardinal DSP16 sound card, which uses the ADSP-2115, told me that someone has done something like this for an Rx with the Cardinal card. He used a DDS oscillator and mixer, converting down to baseband I + Q, and doing lots of processing on the DSP.

Hi,
I have a Grundig Satellit 700 shortwave receiver.
Although a very nice radio, I am not thrilled about the performance
of the synchroneous detector (rumble noise).
I saw a *.mod file for the (older) Satellit 500 model on ftp.cs.buffalo.edu
describing a fix for this problem.
Has anybody undertaken, or does anybody know about a fix for the problem
on the 700 model?
I don't have the circuit diagrams for the radio so I can not check
whether the 500 fix applies to the 700 also.
Which leads to another question:
Does anybody have the diagrams or know where to get them?

Thanks,
Arne

I have a Sat 700 and love it. As for the Sync Detector, simply turning the Bass all the way down eliminated the rumble completely. No mods required. I had the same feeling as you until someone else passed along this simple solution.

I have been interested in doing this completely in software
for baseband modulation. I haven't gotten serious about
it yet (I will probably start with simple fsk) but I don't
see any real obstacles, just a lot of grunt programming.

127. Transverter System Design Help Needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-10 15:13:53 UTC
From: mclendon@brtph833.bnr.ca
Message-ID: <3eu87h$6rs@brtph500.bnr.ca>
Source record: 114678

I am putting together a transverter (28mHz to 146Mhz) system. I
am using Hamtronics separate receiving converter and transmitting converter
kits (which seem to work ok so far). I would like to use this
transverter at the antenna output of 'any' HF transceiver. I do not
want to use direct IF access + low RF drive to operate the txvrtr.

This means that ideally I would like to detect the presence of
the 28mHz rf out from the transciever and drive a t/r relay.
I have designed such a circuit and it works fine; but now
is the problem: when going from rcv to txmt, high level rf
is present at the receiving converter's output for abt 50
milliseconds until the rf detector can operate the t/r relay!
This will likely smoke the receive converter's output (and more!).

Any suggestions on how to protect the receiving converter's
28mHz output from the transceiver's rf during this condition?

I looked at some commercial 2M brick linears with receive amps
that do rf detected t/r switching. They use back to back diodes
from the receive amps output TO ground. Is this a good approach
for my application? If so, may I have a suggestion on what kind
of diodes / circuit would be suitable to sustain 10-20 watts from the
transceiver prior the switchover?

Thanks 73 - Mike - KE4END

For some low power rigs, AM CB rigs for example, that's exactly what
they do. For most ham rigs, the PA is running AB1 even during CW
transmissions, so the drive power is reduced same as it would be
for voice transmission.

The fix on Sat500 did not fix the rumble problem, which seems to come from the phase noise of the PLL ocsillator. The 100 Hz component in the rumble could be reduced by placing few thousand microfarads across the AM +3.5 V voltage. The residual rumble is quite different on different frequencies, both in strength and sound. In some cases it can be cured by detuning by 100-300 Hz. I have not touched any Sat 700, but the analog part of it looks similar on paper, not so in reality. 700 is completely surface mount.

Hello!

I am writing a program that will calculate the Q's of various coils at
different frequencies. However, when I calculate the AC resistance of the
coil (by hand and by computer) I get a value that is less than the DC
resistance that is based just on the wire length. The formula I'm using is:

83.2*(sqrt(f))/d where d=wire-diameter and f=frequency (This is as given
in Terman's)

I notice in other books, and Terman's also, that the formula for Q is:

(2*pi*f*L)/R_series.

Apparently R_series is not the DC resistance of the coil.
My AC resistance is coming out less than the DC resistance.
Can anyone tell me what's going on here?
Just what is R_series?

Thanks!

: why would Pioneer offer car stereos with .7 microVolt sensitivity?
: And, I believe the noise figs. for the ARRL preamps were something
: around .5 dB.

Yes, these low noise figures are quite important for hearing signals bouncing off the moon. Surprisingly, I've never heard of someone actually putting up a huge array to hear FM signals off the moon, though amateurs have put up dozens of yagis to make two way contacts off the moon. The cost of even a $200 preamplifier is often a small fraction of the cost of putting up a huge antenna installation.

To get the ultimate in noise figure you might look at power GaAs FETs. The Mitsubishi 1801 and 2116 are known to work at 2 meters. Unfortunately, I don't know the 1/f corner, below which noise performance degrades significantly. You generally want a wide gate to reduce diffusion noise--you find this with power devices. Such FETs generally cost $50 to hundreds of $$. You might be able to acheive a 0.2 to 0.3 dB NF. A difficulty is that manufacturers don't have the equipment to measure such noise figures accurately. Hewlett Packard's expensive setup has a worst case accuracy around +/- 0.3 dB.

Oh yeah, getting a stable design can be really difficult, but a smart designer with lots of equipment and tools can often find a solution.

I AM A CAVER WHO IS CONSIDERATING A NEW PROJECT. I AM CONSIDERING BUILDING A THROUGH THE GROUND SSB RADIO ON SOME FREQUENCY BETWEEN 32 KHZ UP TO 100 KHZ USING A MAGNETIC LOOP ANTENNA.

PART OF MY CONSIDERATIONS IS USING THIS UNIT FOR COMMUNICATIONS AS WELL AS RADIO LOCATION WORK (IF POSSIBLE). ONE OF THE THINGS I WOULD LIKE TO ACHIEVE IS USING A LOWER FREQ (~ 32KHZ - BEST FOR PENETRATION) AND BUILD AS A VERY LIGHT WEIGHT PORTABLE UNIT (MAYBE BELT MOUNTED). I WOULD LIKE TO WIND MY MAGNETIC ANT ON ITS CASE TO BE USED AS A SELF CONTAIN UNIT FOR SHALLOW PENETRATION. (LARGER EXTERNAL LOOP ANT FOR LOCATION WORK AND GREATER PENETRATION).

IN THE FEW PUBLICATIONS THAT ADDRESS THIS TYPE OF COMMUNICATIONS (SPELOELCTRONICS), THERE IS DISCUSSION ON BUILDING FERRITE LOOP STICK ANTENNAS. THE FERRITE ROD MAKES THE COIL APPEAR AS A LARGER LOOP. IN THE FORMULAS, PART OF THE CONSIDERATION IS LENGTH TO DIAMETER.

WHAT I AM CONSIDERING IS WHETHER I COULD BUILD THE CASE (NON METALLIC) AND COVER THE OUTSIDE WITH A FERRITE SHEET MATERIAL (IF AVAILABLE) AND INCREASE THE EFFECTIVE PERFORMANCE OF ITS SELF CONTAINED ANTENNA. I HAVE NOT BEEN ABLE TO MAKE THIS DETERMINATION (NOT INTELLEGENT ENOUGH AT THIS TIME TO EXTRACT THIS INFORMATION OUT OF ENGINEERING MANUALS).

AND SUGGESTIONS, FORMULAS, DATA MATERIAL, AND AVAILABLE OF FERRITE SHEET MATERIAL, WOULD BE APPRECIATED.

Jim-

A few months ago, I went through my ATs and adjusted the oscillators. It seems there are separate crystals and coils for simplex transmit, -600 and +600 offsets and receive. Fifteen KHz is a little far to drift, so it may be a symptom of a problem. However, it should be within adjustment range, so give it a try.

It is possible the problem was caused by the coil slug shifting due to vibration or being dropped. If so, use of some paraffin or bee's wax, would help keep it from moving in the future.

I suggest you get out the paperwork that came with the radio, and figure out which coil adjusts which function, before you open it up. As I recall, some of the circuit views may have been from the opposite side of the PCB, but it was possible to correlate the parts.

There are differences in parts layout between the IC-2AT and IC-4AT, but the procedure is the same.

Source record: 114693

Hi,

my interest in FM receivers took a significant leap when I found
an Fisher all-tube FM tuner from the early sixties. I will
now start to study RF front ends, IF strips etc. I can easily
find intro text on this topic. I understand ARRL has a new book
out at the more advanced level but I wonder if there are any texts
out there that would fall into a category I'd call "all-out designs" ?

For starters:
I'd like to study the RF stage and see if the 6CW4 tubes now
there can be bettered especially in the noise compartment.

I need to learn the nitty-gritty of mixer stages.

I need to study discreete FM IF strips and how to tune them.
I'd like try a good quality solid state FM IF strip to increase
the selectivity of the IF stage.

And I need to know more about stereo generation circuits.
as the MPX sub-board is lousy and probably hard to adjust.

I am aware that this topic is tangential to the charter of this
list but it hard to know in advance where the gung-ho tuner
enthusiasts hang out.

Thanks,

john 015

If your Terman is like mine, the number he has you calculate for AC resistance
is a multiplicative factor (I can't remember exactly which one you multiply by
what). So I'd re-read the section and make sure you're applying the equation
correctly. It *doesn't* directly calculate the AC resistance by my
recollection.

Bob-

As I recall, the GD-1B has a 3-pin coil socket. The center pin may be ground, for a differential circuit, but I'm not sure. However, only the outer two pins are used for the higher frequency coils.

It seems like the coil pins were approximately 1/8" in diameter, spaced about 3/4". A typical HF coil might be about 10 turns of 18AWG or 20AWG enamel wire, close-wound on a 3/4" diameter, 2" long form. The coil was located near the end of the form away from the pins. The VHF coil was a half turn ("hairpin") of a wire the same diameter as the other coil's pins. The lower frequency coils were full of fine wire ("Litz"?). It should be easy to pick up a signal from the coil, using a short whip antenna on a counter.

If the meter reads up-scale, it is working. The meter reading is a measure of grid current, which is an indication of the amplitude of the oscillation. At lower frequencies, the amplitude is greater, and the sensitivity control must be turned down for an on-scale reading. In addition to dipping when near a resonant circuit, the grid current varies as you tune across its range. When the tube gets weak, oscillation may not be maintained across the entire VHF range.

I think the power supply used a selenium rectifier. Considering its age, I would expect the rectifier and filter capacitors may be bad. I think a silicon rectifier would be an acceptable replacement for the selenium. If the selenium rectifier is not shorted, you can use its terminals for the silicon diode.

There's still a few of us old geezers around. Maybe someone else will be inspired to fill-in the missing details.

145. TS140 TX unlock

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-12 21:54:13 UTC
From: "Colin Schmutter"
Message-ID: <3f48e5$sn2@chopin.bcit.bc.ca>
Source record: 114696

Hi,

I am using a Kenwood TS-140S that has the modification to unlock transmit on all frequencies. (D29 and D31 disconnected)

However the transmitter will still lock below 1600 Khz.

I was hoping to use the rig as an accurate signal generator as well as an HF rig to align another receiver.

Does anyone know how to unlock the transmitter below 1600 Khz so that I can generate a 455 Khz signal and also the Broadcast signals 550 khz to 1600 Khz?

Thanks

Colin (VE7CQH)

Various comments about urban vrs. rural manmade noise and galatic noise are, no doubt, true in a statistical sense. However, actual results will vary in particular cases. Even galactic noise changes depending on what the antenna is looking at.

Earth noise is more constant.

In any event, lower noise pre-amps will allow you to hear more. It just might not be much more.

<stuff NEVER RECEIVED due to lack of returns>

The bead on the output reduces any possible tendancy to oscillate at microwave frequencies. In addition, the untuned output reduces the gain of the stage and prevents any instability on frequency. The vast majority of ham receivers have a fairly low noise figure and adequate system gain to start with...so full GaAsFET gain would simply reduce dynamic range and increase any tendancy to overload.

Yeow! I could write a book about building transmitters from discarded TV sets. For the past couple of years I've grabbed every curb-side discarded TV set I saw; if I was on my bike I would just do the surgery right there and strap the chassis on my book rack.

All my coils are handwound using the above mentioned deflection coil wire. You can use the inductors on the circuit board for your coil forms (or paper towel cardboard cores make good coil forms).

Don't forget that beautiful variable capacitor with built-in reduction gear in the UHF tuner; my latest 40M rig utilizes one. And my future 20M xmtr will also use one.

151. diplexers vs quadrature hybrids

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-13 06:58:15 UTC
From: jks@hal.next.com
Message-ID: <3f58a7$pgl@cronkite.Central.Sun.COM>
Source record: 114702

In a recent article(1), Colin Horrabin, G3SBI, draws attention to the use of quadrature hybrids in series with conventional diplexers for controlling the impedance seen by mixers or post-mixer amplifiers from a downstream crystal filter. This is offered as a low-loss alternative to using the -6 dB pad present in the mixer/amp/filter designs by Jacob Makhinson, N6NWP(2).

My question is this: when using a quadrature hybrid why do you need the diplexer at all? My simulations with ARRL Radio Designer show the hybrid to be completely effective in providing a nearly constant impedance at its' input when used alone. This fact is also pointed out by comments from William Sabin, W0IYH(3).

Can anyone shed some light on this?
Thanks,

john.seamons@sun.com

(3) Chapter 17: "Receivers, Transmitters, Transceivers and Projects", ARRL Handbook 95, pg. 17.7, "In a 90 degree hybrid splitter, if the two modules [downstream of the hybrid] are identical but their identical input impedance values may not be equal to R [system input impedance, 50 ohms], the hybrid input impedance is nevertheless R ohms, a fact that is sometimes very useful in system design. The power that is "reflected" from the mismatched module input impedance is absorbed in RX, the "dump" resistor [connected to a port of the hybrid], thus creating a virtual input impedance equal to R."

Having just built their 4 band regenerative HF receiver kit with
my 9 year old daughter and 12 year old son (actually, they did
most of the work), I'm impressed with the quality and design.

It worked as soon as we powered it up and is very sensitive.
G-10 epoxy board, no components missing, cost about $15 and
an optional case (some drilling and filing required) for $5
additional. The components aren't mil-spec...
the switches and pots are a bit cheap, but they work well,
and I feel I got more for my money than I would have at
Radio Shack...specifically, the actual design semms to have
had a lot of thought put into it.

Our ham club bought 11, one guy hasn't finished his, but *all*
the other 10 came up working perfectly!.

Just a satisfied customer...

>My AC resistance is coming out less than the DC resistance.
>Can anyone tell me what's going on here?
>Just what is R_series?

R_series is just the loss resistance of the coil at the design
frequency. The second formula above is just XL/R, or the reactance
at the design frequency divided by the loss resistance at the
design frequency. That's the classic definition of Q. The coil's
loss resistance is more than just the resistance of the wire.
It can include losses due to the core or support structure, radiation
from the coil, etc.

The first formula you quote is only an approximation, or engineering
rule of thumb. The value it predicts may or may not be accurate for
a particular coil. Make sure you are expressing all the values in
consistent units when using it. Otherwise you may be led far astray.
It's certainly unexpected that you are getting resistance values
less than what the wire tables would give for DC resistance.

Gary

All of this talk about coils has prompted me to jump in. I enjoy building crystal radio sets. I wind my own coils on various forms such as pill containers, vitamin containers, cardboard, etc. I have even created a crude lotus 1-2-3 worksheet for all the calculations (it takes into account the diameter of the coil form and the gauge of the wire. However, I am interested in fooling around with ferrite rods for coil winding but have no idea as to how to modify my calculations to take into account the affect the ferrite rod has on the inductance of the coil. Can anyone point me in the right direction? Is there a book that would give me the correct calculations for winding coils on ferrite rods? Thank you.

From: uid@ornl.gov
Subject: CAVE RADIO

I AM A CAVER WHO IS CONSIDERATING A NEW PROJECT. I AM CONSIDERING BUILDING A THROUGH THE GROUND SSB RADIO ON SOME FREQUENCY BETWEEN 32 KHZ UP TO 100 KHZ USING A MAGNETIC LOOP ANTENNA.

PART OF MY CONSIDERATIONS IS USING THIS UNIT FOR COMMUNICATIONS AS WELL AS RADIO LOCATION WORK (IF POSSIBLE). ONE OF THE THINGS I WOULD LIKE TO ACHIEVE IS USING A LOWER FREQ (~ 32KHZ - BEST FOR PENETRATION) AND BUILD AS A VERY LIGHT WEIGHT PORTABLE UNIT (MAYBE BELT MOUNTED). I WOULD LIKE TO WIND MY
MAGNETIC ANT ON ITS CASE TO BE USED AS A SELF CONTAIN UNIT FOR SHALLOW PENETRATION. (LARGER EXTERNAL LOOP ANT FOR LOCATION WORK AND GREATER PENETRATION).

IN THE FEW PUBLICATIONS THAT ADDRESS THIS TYPE OF COMMUNICATIONS (SPELOELCTRONICS), THERE IS DISCUSSION ON BUILDING FERRITE LOOP STICK ANTENNAS. THE FERRITE ROD MAKES THE COIL APPEAR AS A LARGER LOOP. IN THE FORMULAS, PART OF THE CONSIDERATION IS LENGTH TO DIAMETER.

WHAT I AM CONSIDERING IS WHETHER I COULD BUILD THE CASE (NON METALLIC) AND COVER THE OUTSIDE WITH A FERRITE SHEET MATERIAL (IF AVAILABLE) AND INCREASE THE EFFECTIVE PERFORMANCE OF ITS SELF CONTAINED ANTENNA. I HAVE NOT BEEN ABLE
TO MAKE THIS DETERMINATION (NOT INTELLEGENT ENOUGH AT THIS TIME TO EXTRACT THIS INFORMATION OUT OF ENGINEERING MANUALS).

AND SUGGESTIONS, FORMULAS, DATA MATERIAL, AND AVAILABLE OF FERRITE SHEET MATERIAL, WOULD BE APPRECIATED.

I discovered the Micro Center store just outside of Cleveland, OH at 1349 SOM Center Road in Mayfield Heights, OH (216-449-7000) just off of I-271.

They did indeed have a very good book/magazine department, not to mention a fine selection of hardware & software items. I think that they will give CompUSA a real run for their money.

I found a great book on LINUX there which I had not seen anywhere else. They must have some on-the-ball buyers in the book department.

Tom:

Class C amplifiers are used for FM, typically at VHF and above. I've been using mobile radio PA's for some time as cheap amplifiers for HT's, both VHF and UHF and as repeater TX. The voltage supplying a stage in the PA is controlled by a series pass regulator circuit feeding the PA, with feedback from a "power adjust" pot, a level control ciruit, temperature and reflected power sensors. In small HT transmitters, the "controlled stage" can be milliwatts and class A.

Usually the "controlled stage" is the predriver, the first transistor on the PA board, handling a few watts (5 watts typ). This has the advantage of controlling smaller currents than what you would find thru the final PA transistors. For instance, a 110W PA will consume 20+ amps in the final PA transistors.... current which you don't want to regulate.

There are a wealth of older radios, from GE, Motorola, etc that are great for
amateur repeater PA's or HT amplifiers, and cheaply available (if not even free). Some suggestions are Mitrek, Micor, Pulsar (this one is the best! It is an old IMTS radio with removable PA, complete with it's own power control board, isolator and dummy load.... on UHF, -10 dBm in gets you +47 dBm out.... add a fan and you are fine for continuous duty). Look for a self contained PA that can easily be separated from the main assembly. This is assuming you want to go this route instead of building from scratch.

For situations that don't demand power regulation, just tie the controlled stage to max volts required for full output. If possible, try to extracate the control circuitry though; it makes life easier. Your mileage may vary.

Hope this helps. To all nethams... this is a good newsgroup with actual technical content, unlike the ham-equipment newsgroup (primarily concerned

with out-of-band mods). Good show!

Tony, VE3PEP
ai797@freenet.toronto.on.ca

PS. Why pay for NEW when USED will do!!! Any other repeater hackers out
there? Solar powered repeaters a specialty.

Subject: Series Resistance?

Hello!

I am writing a program that will calculate the Q's of various coils at
different frequencies. However, when I calculate the AC resistance of the
coil (by hand and by computer) I get a value that is less than the DC
resistance that is based just on the wire length. The formula I'm using is:

83.2*(sqrt(f))/d where d=wire-diameter and f=frequency (This is as given
in Terman's)

I notice in other books, and Terman's also, that the formula for Q is:

(2*pi*f*L)/R_series.

Apparently R_series is not the DC resistance of the coil.
My AC resistance is coming out less than the DC resistance.
Can anyone tell me what's going on here?
Just what is R_series?

Thanks!

TEN-TEC, Inc.
1185 Dolly Parton Parkway
Sevierville, TN 37862-3710

Information: 1-615-453-7172
Fax: 1-615-428-4483
Orders: 1-800-833-7373 (credit card orders only)

I visited these folks whilest driving home from Dallas last week. Nice
folks there. Absolutely gorgeous view of mountains when you exit the
building!!!

Please note: TT has two catalogs -- one for their regular HF equipment and
another, smaller one, that features their kits.

As for other companies.... I'd say "Ramsey" but I'd also say "don't waste
your time nor money with them."

A ferrite bead on the drain lead seems to be used to roll-off the gain at higher frequencies due to the increasing loss in the ferrite. Sometimes this prevents oscillation... and sometimes it doesn't.

Often we've no idea what kind of ferrite was used in the prototype, and very little idea what the lumped-circuit equivalent of a ferrite bead would be.

There's also a glaring inconsistency in the way we think about ferrite beads.
On the one hand: "Slip a ferrite bead over the drain lead of a GaAsFET to provide stability while hardly affecting gain at signal frequency".
On the other hand: "Slip a ferrite bead over the DC supply lead to act as an RF choke at all VHF/UHF frequencies".

Can anyone reconcile those two viewpoints as they apply to a GaAsFET preamp?

If not, it all begins to sound like "voodoo electronics"... you go through
the rituals because the spell sometimes works, but you don't understand why.
For "ferrite bead" read "dead chicken" ?

: why would Pioneer offer car stereos with .7 microVolt sensitivity?
: And, I believe the noise figs. for the ARRL preamps were something
: around .5 dB.

Yes, these low noise figures are quite important for hearing signals
bouncing off the moon. Surprisingly, I've never heard of someone
actually putting up a huge array to hear FM signals off the moon,
though amateurs have put up dozens of yagis to make two way contacts
off the moon. The cost of even a $200 preamplifier is often a small
fraction of the cost of putting up a huge antenna installation.

To get the ultimate in noise figure you might look at power GaAs
FETs. The Mitsubishi 1801 and 2116 are known to work at 2 meters.
Unfortunately, I don't know the 1/f corner, below which noise
performance degrades significantly. You generally want a wide
gate to reduce diffusion noise--you find this with power devices.
Such FETs generally cost $50 to hundreds of $$. You might be able
to acheive a 0.2 to 0.3 dB NF. A difficulty is that manufacturers
don't have the equipment to measure such noise figures accurately.
Hewlett Packard's expensive setup has a worst case accuracy around
+/- 0.3 dB.

Oh yeah, getting a stable design can be really difficult, but a
smart designer with lots of equipment and tools can often find
a solution.

Yeow! I could write a book about building transmitters from discarded
TV sets. For the past couple of years I've grabbed every curb-side
discarded TV set I saw; if I was on my bike I would just do the surgery
right there and strap the chassis on my book rack.

All my coils are handwound using the above mentioned deflection coil wire.
You can use the inductors on the circuit board for your coil forms (or
paper towel cardboard cores make good coil forms).

Don't forget that beautiful variable capacitor with built-in reduction
gear in the UHF tuner; my latest 40M rig utilizes one. And my future
20M xmtr will also use one.

>out there that would fall into a category I'd call "all-out designs" ?

Heyward's book, _Introduction to Radio Frequency Design_ is a good
book, as is Chris Bowick's _RF Circuit Design_, I recomend them both,
but if your primary interest is receivers, then Rohde's _Communications
Receivers: Principles and Design_ should be on your purchase list as
well.

>For starters:
>I'd like to study the RF stage and see if the 6CW4 tubes now
>there can be bettered especially in the noise compartment.

No problem, most solid state designs will blow the old 6CW4 out
of the water, even tube designs using tubes like the 416B will
do better.

>I need to learn the nitty-gritty of mixer stages.

Ah, that's where a lot of magic lives. Diode ring mixers have
dominated for a while now, but active Gilbert cell mixers are
coming on strong. And don't neglect to pay attention to the
local oscillator. A clean LO can make a world of difference.

>I need to study discreete FM IF strips and how to tune them.
>I'd like try a good quality solid state FM IF strip to increase
>the selectivity of the IF stage.

There's plenty you can do to improve the Fisher's IF strip, but
this is a less critical area, and tube circuits still do a good
job here. Of course they can be replaced with a single subsystem
chip with a ceramic filter, and give a performance gain. The
stagger tuning employed in the old tube IFs is a pretty coarse
compromise. A monolithic filter will likely do better. Eliminating
the tube shot noise will be a win in and of itself.

>And I need to know more about stereo generation circuits.
>as the MPX sub-board is lousy and probably hard to adjust.

There's less good general literature on this (at least of which
I'm aware). I'd recomend looking to the professional publications
for the broadcast industry, and to IC manufacturer's application
notes for information on this subject.

There's another area where you can likely make great improvements
in the receiver. That's in the detector and post-detector amplifier.
There are several detector designs which will give better linearity
than the Fisher offers, (a pulse counting detector could be a good
choice), and the post-amp could really stand cleaning up, and flattening,
and broadening response for best sound.

>
>Can anyone shed some light on this?

The diplexer serves two purposes, it acts as a broadband termination
for the mixer, and it serves as a dissipative pre-filter for the
downstream filter. As you've noted, the hybrid can serve for the
broadband termination, but hitting the downstream crystal filter
with strong out of band signals is not a particularly good idea.
The hybrid doesn't address this at all. Of course if you are using
adequate pre-selection before the mixer, this may not be an issue.

Ferrite beads are not much use at UHF, they are effective at VHF and below. I think their function is to prevent low frequency (VHF/UHF) paracitics in the pre-amplifier. The bead will reduce the gain, even at the signal frequency. That does not mean it will significantly increase the noise but it will certainly have an effect on stability. Better to design a stable amplifier in the first place, by ensuring the gain is not some ridiculous 20dB figure but more like 13 db or lower with two stages for high gain if required.

161. PCBs from Laser Print/Photocopier

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-13 16:29:07 UTC
From: kirkland@bgtys22.bnr.ca
Message-ID: <3f69oj$e27@bmerha64.bnr.ca>
Source record: 114712

I have just finished my first try with the "Toner Transfer System"
by DynaArt Designs (available from All Electronics Corp. 818 904-0524)
and experience great success. This system uses a special paper with a
water soluble coating which makes the paper backing easy to remove after
the transfer is done. - Works like a charm. I did two PCBs yesterday and
they both turned out great on the first try. The only problems that I found
are that there are problems with the toner sticking around the board edges
and that on large areas, e.g. ground planes, there is some bleed through however
all of the traces were solid - the smallest trace was 0.02".

The boards were done using a PADSDEMO package and printer out on an HP 600 dpi
laser printer using this paper. The key to using this is to have a laser printer
(or photocopier) that prints as black and as solid as possible and to use the
proper iron temperature to iron on the artwork. What I did was to first print
the artwork onto an overhead transparency and to try and iron this onto the
PCB board. This didn't work out too well but it did give me a good feel for
what a good temperature and iron time should be. I also recommend following
the suggestions that come with the instructions.

I am very impressed with this product and I have found it to be far superior than
the tech film. An advantage with this system is its ability to make color face
plates. Print the image onto the special paper, coat the image with a few coats
of laquer and then imerse the paper in water and you now have a decal for the face
plate.

A note on using the PADSDEMO package:
while the package limits you in the number of components you can use it is
suitable for doing small PC Boards and will not let you print multiple boards
on a single 8x10 sheet if the sum of the board components is greater than the
limit. A way around this so that you can fill an 8x10 sheet up with boards so
as to maximize your use of the transfer paper is to print the artwork out in
a postscript format, one postscript file per board. What you then do is to
edit each file (except one which will be the initial file) and strip off the
initial postscript commands, that the lines from

```
%!PS-Adobe-2.0^M
....
%%EndProlog^M
```

and you should be left with the following lines

```
gsave
Init
8000 10500 Clipto
0 0 translate
0 rotate
```

....
grestore
showpage

strip off the showpage command from each of the files except for the last file (showpage prints out the document as near as I can figure)
then append all of the files together starting with the first one with has the initial postscript prolog commands and ending with the file that ends with the showpage command - make sure you stripped off the showpage command from the 1 st file. You can place your boards anywhere on the 8 x 10.5 " page by editing the 0 0 translate command for each board. The origin is at the bottom left hand corner. Not there is an implied 1/4" border around the page as setup in the prolog commands in the postscript file. For DOS machines fetching the GS (ghost-script package & GSVIEW packages) helps as it allows you to view the PS file before printing it.

Hi,

I am using a Kenwood TS-140S that has the modification to unlock transmit on all frequencies. (D29 and D31 disconnected)

However the transmitter will still lock below 1600 Khz.

I was hoping to use the rig as an accurate signal generator as well as an HF rig to align another receiver.

Does anyone know how to unlock the transmitter below 1600 Khz so that I can generate a 455 Khz signal and also the Broadcast signals 550 khz to 1600 Khz?

Thanks

Colin (VE7CQH)

>gate to reduce diffusion noise--you find this with power devices.

I disagree. A power MESFET (wide gate) is not a good choice for low
noise operation compared to a low noise FET (much narrower gate).

Noise Figure F (the Fukui equation):

F=1+2*pi*K*f*Cgs*[(Rg+Rs)/gm]1/2 x 1E-3

K=constant
f=frequency
Cgs = gate source cap
Rg=gate resistance
Rs=source resistance

Rg ~ 17*z*z/(WhLg)

z = unit gate width in mm
W=gate width in mm
h=gate metallization height in microns
Lg is average gate metallization length in microns

All other things being equal, a wider gate (characersitic of a power
MESFET) will increase Cgs and Rg, thus increase the noise figure.

Best noise figure occurs near the knee voltage. For a power FET, the
current will be much higher at the Knee that for a low noise MESFET with
a smaller gate width. The power FET will run warm even at this voltage,
thus the transistor will heat up further adding to poor noise performance.

166. New RF CAD program

Newsgroup: rec.radio.amateur.homebrew

From: lukes@iaccess.za
Message-ID: <3f6nkr$19j@cstatd.cstat.co.za>
Source record: 114717

I am new to the net and first posted this as "ARRL Radio Designer". Something went wrong when I posted it, reducing the message to a single "y".

So, once more....

I saw an advert for a program called "ARRL Radio Designer" in the December 1994 issue of "RF design". According to the advert, it is a derivitave of Super-Compact (well known to RF engineers and used for frequency-domain circuit analysis).

Does anybody know the program, or better still, has used it? I first posted this at sci.electronics.cad and some helpful people directed me to this newsgroup. There seems to be general interest in the program, so please post responses in this newsgroup.

I have some questions:
1. Does it support Smith chart outputs?
2. Is a model for coupled transmission lines included?
3. Can new circuit models be created by the user (like SPICE) or are the models encrypted?
4. Do you like it?

Thanks (and thanks for the witty comments to my blunder :-))

I am sorry if this shouldn't be posted here, but I want to make sure that every one knows about us.

First let me introduce myself. My name is Mike and I am the Public Relations manager for the Husky Amateur Radio Club here at Michigan Technological University. Now for the info. on the special events station.

In a few weeks we here at the univ. are having an event called Winter Carnival. This event is even bigger than our homecoming. We (HARC) will have a special events station set up for 24 hours starting Febuary 2, 1995 at 6AM in the morning and running until 6AM Febuary 3, 1995. Whoever contacts us will receive a high-quality certificate from us special made for Winter Carnival and our special events station. It would look great framed on the wall!

Right now we are unsure on the freq we will be running on so stay tuned for more information as to what freq we will be on or email me at cmlong@mtu.edu

Thanks for your time and we hope to here from you!

The PR Guy,
Mike

> In regards to quadrature hybrid being placed after a mixer - what
> is a quadrature hybrid?

A quadrature hybrid is basically two couple transmission lines, one quarter wavelength long. It can be use to split rf siganls into two components, each with half the total power (less losses) and 90 degrees apart in phase. It can also be used in reverse to combine two signals that are 90 degrees apart in phase. There are four ports, the sum shows up in one port, the difference at the other. They are quite commonly used to combine two rf amplifiers. One splits the signal to drive two amplifiers, another combines the outputs to deliver the sum to the output. You need to think carefully about the 90 degree phase shift so you know which port gets the output. It is essential to connect a 50 ohm load to the unused port.

> Does anyone know whats so special about the professional detectors (ie. HP423) that makes
> them so flat and broadband without apparent impedance matching?

A broadband load resistor is essential. Also the diode packaging can have an effect on performance. For homemade try chip resistors. Two 100 ohm in parallel is a good way to go. Still, flat output from 500-1000 MHz is a pretty tall order.

Used 423A's can be had for around $100 from Tucker in Garland, TX and they are definitely not the cheapest source around. Beware of new, inexpensive ($50) from some suppliers, they are usually not very flat at UHF.

173. FBTO update

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-16 02:37:23 UTC
From: Mike.Czuhajewski@hambbs.wb3ffv.ampr.org
Message-ID: <1995Jan15.213723.7034@wb3ffv.ampr.org>
Source record: 114724

There was a bit of discussion recently about FBTO (From Beverage To Oscar), which is a computerized data base of ham radio articles. Please forgive me for cross-posting this to both r.r.a.homebrew and r.r.a.misc; I don't remember where the original discussion was. (Also posted to qrp-l@netcom.com; many of the people on that list do not have access to USENET but might find this of interest.) I talked with the author today (Rich Rosen, K2RR), and got an update on its status (the data base hasn't been updated for a few years).

For the uninitiated, FBTO is an incredibly useful bibliography program--it allows you to search for articles on a particular subject in the major ham magazines. As a homebrewer I find it quite useful, especially since I have QST back to 1960 and every issue of Ham Radio ever published, as well as access to QST back to the 20's and every issue of CQ and 73.

Being a computerized data base, FBTO is inherently superior to any annual index ever published in any magazine, and even superior to the 5 year cumulative indexes that Ham Radio published. You can do a single, quick search on any particular phrase you want (using the list of words and abbreviations that are used in the data base); it searches out all articles with that phrase in the description field, regardless of magazine, and regardless of year. (Just try finding every article ever printed in CQ, QST, Ham Radio, 73 and RadComm on some topic, such as crystal oscillators, by sitting down with a three foot high stack of December issues and digging thru all those annual indexes!)

One thing which makes it exceptionally useful is the extensive cross-indexing. Many times I've searched for info on things such as attenuators, crystal oscillators, VFOs, etc, and when I went to look at the references FBTO gave me I would find that they were sometimes articles which happened to contain those things but did not mention them in the title. For instance, an article with a title about 2M "fox hunting" might contain a circuit for an attenuator--if you were just looking at annual indexes, you'd never think of looking at an article about hidden transmitter hunting!

The version of the program that I have access to at a local ham store is 2.0, and Rich said the current version is 2.01. (The store has a ham radio library, open to all, with a massive collection of back issues of the major magazines and a number of related books, and has a computer with FBTO on it.) As I recall from a previous conversation with Rich, the differences between 2.0 and 2.01 were minor and it did not contain an updated data base. The latest

program covers articles through December 1990. He indicated that the update he is currently working on will push the cutoff date up to December 1994, and the additional entries will cover only the major ham magazines--QST, CQ, 73 and RadCom (journal of the RSGB in the UK). He wasn't sure if he would add Communications Quarterly (the successor to Ham Radio), but I told him that would be a very good idea.

He will also be changing the basic search program somewhat. He has had feedback from users (including me) about some minor improvements that could be made. As for sales, it continues to move along--he indicated that somewhat over 1700 copies have been sold, although he believes there are considerably more copies in use. He is considering some sort of anti-copy protection for the future, to protect his interests; after all, this IS a major effort and consumes a tremendous amount of his free time. We discussed the use of hardware protection keys ("dongles"), something that I see at work all the time on the expensive engineering programs we use. He may go that route if the added cost is minimal. (An advantage of that method is that you can easily make backup copies of a program for safety but only the person having the hardware key can run it.)

Rich also said he might make yearly updates to FBTO available at low cost to registered owners.

I've had access to FBTO for several years now. It's been a love-hate relationship due to some of the quirks (which are admittedly minor), but for the most part it's "love", and I've found it to be incredibly useful and well worth the money. (Actually, it wasn't my money at all since I use the program at the ham store on their computer, but when the updated version comes out I'm going to finally break down and get a copy for home--and it WILL be worth the money!)

Disclaimer--I have absolutely no connection with K2RR or FBTO except for being a satisfied customer and occasional pain in the neck about suggested improvements.

Message-ID: <1995Jan15.220044.7884@wb3ffv.ampr.org>
Source record: 114725

I was browsing through the ads in the back of the Jan 95 QST on Christmas Eve and got my best Christmas present of all: the announcement of a "new" book from ARRL. Not just any book, but a reprinting of a classic which is very high on my list of "books that are worth stealing from a friends library even if it costs me a friend". :-)

The ad is on page 170, with a red background, and says "Design your own HF, VHF and UHF equipment!" The name of the book is Introduction to Radio Frequency Design by Wes Hayward, W7ZOI. The fine print tells it all--they call it a "timeless reprint". It was written in 1981, and I've had access to copies over the years. At work, some of the RF engineers have it on their bookshelves. Until now it was only available as a college level textbook (as far as I know) and we all know what that does to the price! I don't know if it's still available from Prentice-Hall, but if it is, it has to cost considerably more than the $30 ARRL wants for it. I presume this is a paperback, the size is 400 pages, and the ARRL version even comes with a 3 1/2" disk for IBM-compatibles with some design programs to accompany the text.

Those of you who are already familiar with the book will probably understand why I drove to work as soon as I saw the announcement (even though it's Christmas eve!), unlocked the building and FAXed my order off right away. For those who don't know it, in a very general way it's along the lines of the ARRLs Solid State Design for the Radio Amateur (by Hayward and DeMaw) but without all the projects, but that's really not a good comparison. It is much larger and much more in depth. On the bookshelf of the technically inclined ham it would sit alongside that book and RF Circuit Design by Chris Bowick, WD4C (1982, ninth printing 1992, currently available from Howard W. Sams). As to the level of difficulty, it's more along the lines of the Bowick book than SSD; this is definitely not for the beginner, although the beginner could still pick up a lot from it. The technically oriented ham will probably love the book. (I do.)

The chapter titles, at least in the original version, are Low Frequency Transistor Models; Filter Basics; Coupled Resonator Filters; Transmission Lines; Two-Port Networks; Practical Amplifiers and Mixers; Oscillators and Frequency Synthesizers; The Receiver: An RF System.

I was overjoyed to see ARRL publish this book at a price aimed at the hobbyist rather than the engineering textbook market. It deserves to have a much wider audience in the ham world, and this should help,

due to the price and availability from a widely known ham publisher.

And if anyone from ARRL reads this and is wondering what else we techies might be interested in seeing, how about a reprint of Zverevs monster on filters? I understand it's out of print now, and anecdotal evidence suggests it's a frequently stolen book from libraries! (The boss has one in his private technical library but we all know better than to steal that one!) Then there's the DeMaw book on ferromagnetic cores...

Standard disclaimers apply--I have no interest in any of the items mentioned except as an enthusiastic consumer, and do not work for any of the entities involved. (This is being posted to both r.r.a.homebrew and the QRP mailing list.) 73 DE WA8MCQ

: inside it?

: The case is about 2.5" X 1.5" X 0.5"

: "AUDIO, VIDEO, +12V and GROUND"

This is likely a TV modulator. You put in audio and video, and get out a
channel 3 or 4 modulated TV carrier. Sometimes these units will have a
small switch that will let you select between chan 3 and 4.

Later,

Source record: 114727

klineda@univscvm.csd.scarolina.edu:

:I am writing a program that will calculate the Q's of various coils at
:different frequencies. However, when I calculate the AC resistance of the
:coil (by hand and by computer) I get a value that is less than the DC
:resistance that is based just on the wire length. The formula I'm using is:

:83.2*(sqrt(f))/d where d=wire-diameter and f=frequency (This is as given
:in Terman's)

:I notice in other books, and Terman's also, that the formula for Q is:

:(2*pi*f*L)/R_series.

:Apparently R_series is not the DC resistance of the coil.
:My AC resistance is coming out less than the DC resistance.
:Can anyone tell me what's going on here?
:Just what is R_series?

If L is the inductance per unit length, R_series is the ac resistance per
unit length, which is

83.2 * 10^-6 * sqrt(fmhz) / dia for copper wire

where the unit length and diameter are in the same units. For example,
#12 wire (80.8 mils diameter) at 1 MHz has an RF resistance of 1.03
microohms per mil, or 12.4 milliohms per foot vs. 1.59 milliohms per
foot at dc.

187. GaAsFET Update

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-17 16:00:09 UTC
From: reichert@rtsg.mot.com
Message-ID: <3fgpi9$kaq@delphinium.cig.mot.com>
Source record: 114738

This is the lastest from CEL on the 3sk124 and 3sk205
Dual Gate GaAsFET devices per Steve Pavlich.

The 3sk124 and 3sk205 are now offered in Surface Mount
only. The respective part numbers are NE25139 and
NE25339. The leaded version has been discontinued!

Although there is a $50 dollar min. order Steve "may"
sample some. I make no promises for CEL but it can't
hurt to ask. Normal pricing (qty 100) is 80 cents each
for the 3sk124 and about double that for the 3sk205.

The low cost single unit pricing is no longer in effect.

Oh well, there's another good deal down the drain!

CEL Rep: Steve Pavlich @708-241-3040
6823 Hopson Valley Rd.
Woodridge, IL. 60517

Disclaimer: I have no connection with CEL other than
a user of their devices in my own Ham Radio circuits.

Lets see, as I recall you're interested in a CB antenna. The major problems with mobile antennas are structural, and especially so for CB, and HF antennas in general. A quarterwave CB whip is 108 inches tall. That requires a strong connection to the auto body, and a strong and flexible whip to survive windloading at speed, and to survive hitting low hanging limbs and parking decks. While it's possible to fabricate your own base mount, they're so cheap that it's better just to buy a bumper or body mount ready made. The whip should be stainless steel for the required strength and flexibility. Efficiency will be improved if the whip is copper plated. Again, it's easier just to buy a ready made whip.

Magnet mounts aren't suitable at CB frequencies since they don't offer a low enough capacitive reactance at those frequencies to couple to the current mirror in the body. Shortened coil loaded antennas give up some efficiency compared to a full size whip, but will do tolerably well if mounted high on the vehicle with a good through hole mounting that gives good current mirror coupling. Shortened antennas have a low radiation resistance so it's vital that all other losses be minimized for best efficiency. Good connections and good cables are essential.

Are there any homebrew plans out there to build bandpass/reject duplexers
for 2 meters (600 khz splits) ? Any info would be great ..

: >My AC resistance is coming out less than the DC resistance.
: >Can anyone tell me what's going on here?
: >Just what is R_series?
: >

: If your Terman is like mine, the number he has you calculate for AC resistance
: is a multiplicative factor (I can't remember exactly which one you multiply by
: what). So I'd re-read the section and make sure you're applying the equation
: correctly. It *doesn't* directly calculate the AC resistance by my
: recollection.

The original posting didn't make it through to here yet, but I gather this
quotes all of it anyway...

The first equation will be quite accurate so long as the wire diameter is
more than a few times the skin depth. But clearly, the resistance does not
go to zero as the frequency goes to zero, as this formula would suggest!
That's independent of whether it's complete or a multiplicative factor.
Also, you should put units on the formula: is d in inches, feet, mils,
microns, ...? What units does the 83.2 carry? The one I'm used to is
0.996*10^-6 ohm-inches/foot-sqrt(Hz) * sqrt(f)/D where D is wire diameter
and f is frequency -- in inches and Hz to make the units come out right.
That's all for copper wire; adjust by sqrt(specific resistance) for other

materials.

The second equation is correct, where R_series is the _effective_ series resistance. This won't be what you get from the first equation, which is for a straight, isolated wire. As someone else pointed out, the Q can be affected by things other than the copper resistance, though this would be a decent starting point. But the first formula won't even do a good job predicting this...

An example: 18 gauge wire, diameter = .040". Frequency 10MHz. Resistance about .079 ohms/foot. Assume a coil radius 1" length 2" 30 turns. Approximate inductance about 31 microhenries. Wire length about 189 inches or 15.7 feet. Resistance about 1.24 ohms, according to first formula. Expect Q to be _about_ 1950/1.24 = 1572 from this. This is far from what the real Q will be! See "Reference Data for Engineers" (Howard Sams) in the "Fundamentals of Networks" chapter; there is a reasonable estimation of coil Q for practical single-layer solenoid coils as used at high frequencies. It would predict Q about 600 for this (isolated) coil. Even that seems a bit high. (If anyone is interested, I reduced the graph in the book to a formula you can use in a program or spreadsheet...)

PRESS RELEASE

JANUARY 17, 1995

WVARA ANNOUNCES WEB PAGE

The West Valley Amateur Radio Association (WVARA) is announcing the development of it's own home page. WVARA joins the ranks of many other amateur radio clubs in having a home page with links to other points of interest to other hams. This includes links to other clubs, the FCC gopher server, all of the amateur radio related UseNet groups and other Web points of interest to hams.

The WVARA home page is run in conjunction with a law-oriented home page, providing links to most legal-related web points of interest.

The WVARA home page can be visited at:
http://www.portal.com/~twise/

For more information, e-mail twise@sparta.sjsu.edu

JT> I see that Crystal Radio Kits are getting some play here. I bought one
JT>last fall from American Scientific & Surplus, Skokie, IL for $10.00 and
JT>it works well. Kind of a nostalgic thing as I used to make them from
JT>scraps out of my Dad's TV & Radio Repair Shop.
JT> Joe
JT> N4NAS Glasgow, KY

Hello Joe! Do you have the address or phone number for that company?
BTW - I THINK I used to work you on 2m FM a few times about 10-12 years
ago if I'm not mistaken. I lived in Nashville, TN, and travelled up into
central/Western KY a lot. Do you know Owen Frisbee from over by Land
Between the Lakes? Iforget his call, and lost touch with him and a bunch
of the guys over there between Paducah and your area.

198. pros and cons of coil squeezing?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-18 14:25:06 UTC
From: ptaber@xis.xerox.COM
Message-ID: <9501181025.A16697@xis.xerox.com>
Source record: 114749

Hi --

I built a Ten-Tec 6M transverter, and love it, but have a question. At the end of the manual, after aligning the TX section it says you can play around with squeezing or pulling the coils to get some extra output over the rated 8 watts. I did and got a screaming 12 watts out, but wonder what I'm paying in return? Is the price just higher current consumption, or could might there be unwanted output products? (spurs, harmonics and the like.) Naturally, I would expect products that were there at eight watts to scale up with 12 watts, but would/could there be new Bad Things? Could the ones that were there before be enhanced more than scaled? This was my first project that actually put RF on the air, so I've never looked into this before.

What say you?

If you're too cheap to spring for the $12 per year, you're certainly not
going to want to buy any of the parts required to build any of the projects.

200. Re: FM broadcast receivers

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-18 16:11:06 UTC
From: mack@mails.imed.COM
Message-ID: <9500187904.AA790453664@mails.imed.com>
Source record: 114751

I have copied John's post below (I'm too lazy to put in the '>' in front of every line)

Stagger tuning refers to the method of tuning the entire IF chain to get a fairly flat response about 150 KHz wide. The Q of the IF transformers at 10.7 MHz was fairly large so that they could get steep skirts, but they needed to offset the center frequency of each tuned circuit to be able to also get the bandwidth desired. TV sets had an even tougher time getting a flat response of 5 MHz wide at 45 MHz IF. Now they just use ceramic filters in FM sets.

As to the use of 6AU6 tubes, these tubes were common in FM sets because of the narrow gain characteristics. They did not have much in the way of AGC capability. Most FM receivers used a 6CB6 somewhere as the limiter.

I am not aware of ANY tube being used as quadrature detector (and I worked with a lot of old tube type FM receivers). A quadrature detector requires a lot of active devices and a balanced mixer. This was VERY difficult to do with tubes. I suspect that what the 6BN6 drives was instead a ratio detector which was considerably more tolerant of AM on the signal than a Foster-Sealy discriminator. However, the 6BN6 is listed as a "gated beam pentode". This may indicate that it might have been used in some type of a pulse conversion type of detector.

A quadrature detector is used primarily because it requires only one tuned circuit to work and requires basically NO tuning to work properly. A ratio detector or discriminator is very sensitive to circuit Q and to the tuning of the two tuned circuits.

You should be able to order a crystal from International Crystal (ICL) for this radio. Once you get the service information for it, it should have the necessary information to order the crystal. Don't worry about drift. There is probably a variable capacitor used to set the crystal on frequency. These radios were so tolerant of frequency drift that a crystal should not have any problem staying on frequency even though it will drift slightly with frequency.

You probably want to order a crystal 10.7 MHZ ABOVE the frequency you want to receive. ALL FM radios that I am aware of are designed to have the local oscillator above the frequency being received. Of course, this is mostly so that the span (as a percentage of the lowest frequency) is smaller. i.e. 77.3 MHz to 97.3MHz is a 26% change in frequency where 98.7 MHz to 118.7 MHZ is only a 20% change and easier to make work properly (at least back then). The other concern is where to put the image frequency. Back then you were more likely to get interference from a TV station than from a mobile radio.

****

John (From: CC015012@brownvm.brown.edu (john 015)) wrote:

Hi,

I posted a few days ago, seeking advice regarding an FM tuner and what written material I should consult to learn more about this fascinating topic. I'm still waiting for a schematic for the Fisher tube tuner but in my eagerness I have looked at the circuit and consulted all the books available to me locally.

The broadcast wide FM-IF stip consists of four 6AU6/EF96 tubes I think. "Think" because according to the book I read no limiter(s) is needed when you use the 6BN6 tube for detection. But "think" also because muting, squelch and such things might be one of these tubes.

Apparently the 6BN6 tube is a quadrature FM detector and the frequency modulated signal need not be of constant amplitude ("limited") for this type of detection to work - it's quite (totally ?) insensitive to amplitude variations in the frequency modulated signal coming down the IF strip.

Last time I posted I was told that the detection in old tube tuners could stand some improvement. Knowing what I know now, is the quadrature detector a sigificant step in the right direction or am I still far behind say "pulse counting detection schemes" ?

My second question relates to what was called a "staggered tuned" IF strip. I have not come accross the term staggered tuning before so I wonder if a kind sould would explain the basic concept and why it was chosen in the tube amplified IF strip of the early sixties ?

Lastly, say I want to concentrate on receiving only one station. (The tuner in question is the Fisher FM-1000 and it has a compartment for a xtall tuned RF stage. I understand broadcast engineers would want this to monitor their own stations).
I want to receive 102.5 so I looked for crystalls in 10.7 MHz down from that, 91.8 MHz, but no such luck. What would be the best way to generate locally a fixed frequency and maybe still have it adjustable to compensate for drift ?

Thanks again,
john

klineda@univscvm.csd.scarolina.edu wrote:

:I am writing a program that will calculate the Q's of various coils at
:different frequencies. However, when I calculate the AC resistance of the
:coil (by hand and by computer) I get a value that is less than the DC
:resistance that is based just on the wire length. The formula I'm using is:

:83.2*(sqrt(f))/d where d=wire-diameter and f=frequency (This is as given
:in Terman's)

:I notice in other books, and Terman's also, that the formula for Q is:

:(2*pi*f*L)/R_series.

:Apparently R_series is not the DC resistance of the coil.
:My AC resistance is coming out less than the DC resistance.
:Can anyone tell me what's going on here?
:Just what is R_series?

R_series MUST be at least as large as the DC resistance of the coil. A common error in applying formulas is getting the units wrong. Using cm instead of mm or cm instead of inches etc. will cause the answers to be wrong. (I wrote a program for Cohn filters that consistently gave negative capacitance values until I realized that F was in MHz not Hz). The problem with the formula above, as noted by another person, is that it only accounts for AC effects on resistance. You probably should add the DC resistance to the AC resistance calculated from the formula above. If you read the text again carefully, you will probably find that this is what is being described.

One of the problems you will have in accurately calculating the Q of coils at higher frequencies involves the effects of mutual capacitance. As the frequency increases a coil can in fact change from having inductance to looking more like a lossy capacitor. This REALLY messes up the calculations.

Nothing "likely" about it! This is a computer type TV modulator. What tips you
off that this is a computer type modulator is that it uses an RCA connector for
the output instead of an F connector. Given the 221-??? part number I'd bet
that this is a Radio Shack part.

Who said anything about me being cheap?

Some things aren't worth $12/year. I wanted to know if QEX were WORTH it
(having never seen a copy personally).

So far the responses have been overwhelming in support of QEX, so it looks
like ARRL will get $12 more from me this year.

WE@>After a recent trip to my local Junk Emporium, I came home with a
WE@>box labeled "converter" with the first word burnt off. It had 2
WE@>"F" connectors and a "N" connector. Inside was a 8 pin metal
WE@>can about the size of a TTL chip, although about 3/8th of an

Interesting find....wish my local junk emporium had such finds. (G)

WE@>inch high. Markings on the outside : MCL SC-90 Is this a uhf

MCL = Mini Circuits, P.O. Box 350166, Brooklyn, NY 11235-0003
(718) 934-4500, Fax (718) 332-4661

As for the SC-90, looks to be a Splitter/Combiner although the latest
catalog I have doesn't list an "SC" by itself. Usually the number gives
the highest frequency the device will operate at. There are several
power combiners listed with a 90 as the suffix: SCPQ-90, 55-90 mhz,
surface mount; PSCQ-2-90 (the package you describe), 55-90 mhz, 8 pin
can. Note that the surface mount unit has a maximum power rating of .5
watts where the "dip can" is 50 mW. Both units are 50 ohm impedance,
2 way - 90 degree.

WE@>mixer? The PCB was etched with UHF style tracks. Oh yes, the
WE@>one pin is insulated with a blue color while the others are lime
WE@>green. Any guesses on this one? 73 de NS8O Greg

My guess is that the SC-90 was changed to the PSCQ-2-90. You can
contact Mini Circuits to be sure. The blue pin denotes pin one.
Suggested price is $24.95 in quantities of 1-9. They also make a large
selection of other devices from amplifiers to diode mixers to
directional couplers. Hope this helps...

I need to know if anyone has seen instructions in any book or magazine that tells you how to build a simple CW ID'er. The application I wish to use it in is for a repeater I'm building up. It is a commercial repeater with an autopatch, but the controller only controls things such as time out funtions, and squelch tails. It never ID'ed, so I need to install a simple board to do this every 10 minutes when the repeater is in use. Any suggestions?

Bill Schaff (schaff@iiiv.tn.cornell.edu) wrote:

: I disagree. A power MESFET (wide gate) is not a good choice for low
: noise operation compared to a low noise FET (much narrower gate).

: Noise Figure F (the Fukui equation):

: F=1+2*pi*K*f*Cgs*[(Rg+Rs)/gm]1/2 x 1E-3

: All other things being equal, a wider gate (characersitic of a power
: MESFET) will increase Cgs and Rg, thus increase the noise figure.

Experimental results indicate otherwise at 2 meters and 222 MHz. See typical VHF NF contests results or the 1990 Central States VHF proceedings. "Power GaAs FET Preamps" by Kent Britain, p. 6-8. Perhaps the equation doesn't account for the noise generated by placing a very large field across a crystal. This can be on the order of KV/cm, due to the very tiny gate widths.

Maybe you could arrange to have some preamps brought to the Central States VHF conference for a comparision. I can remember to bring my 0.2 dB NF 144 MHz preamp and the 222 MHz one that measures even lower! Both use the MGF 1801 power GaAs FET. I also bring them to the Eastern States Conference, but I'm usually the one tasked with making the official measurements.

There is an easy to make cw id'er in a Sams book titled " The 555 Timer
Applications Sourcebook" by Howard M Berlin. I've used that circuit several
times and it worked fb for me. I like it because it uses easy to obtain parts
and no prom/ eprom is necessary.

Once a lossy transmission line, or a poor antenna, degrades the SNR
of the system, no amount of amplification, even from a perfect preamp
with zero contributed noise, will recover that SNR. Hence the reason
we like to put the preamp right at the antenna.

There certainly could be unwanted products produced by too heavily
loading the stage. Tuning for maximum smoke is generally a good way
to get spurs, harmonics, and IMD. A look at the output with a spectrum
analyzer is highly recomended.

These used to be popular in the days before single chip microprocessors.
Basically, a gated oscillator drives a counter which addresses either
a diode matrix or a EPROM which has the dots, dashes, and spaces for the
ID programmed into it. The diode matrix is bulky, and uses a ton of diodes,
burning a EPROM is better if you have access to a burner. Your gated
oscillator can be a 555, and it's oscillation frequency will be your
code speed control. The counter needs to be resettable, and you need
some glue logic to gate the count off after the ID finishes. You can
use another 555, gated by the EPROM output, to generate the MCW tone,
and yet another 555, or other timer chip, for the 10 minute timer.

Of course all this can be programmed into a single chip micro which
can also attend to the other repeater control chores. That's the
way things are generally done today. One of the little Stamp controllers
would be fine for just making an IDer. Digi-Key sells them for around
$20. Several of the larger distributors will burn your code into one
for a small charge.

Source record: 114622

A 7805 is a three-pin, flat-pak voltage regulator, rated at 5 VDC regulated output at 1 amp. If you intend to run it at 1 amp, heat-sink it to the chassis or a sink. Input voltage can be up to (I think) 25 volts, but it is commonly used to provide 5 volts from a 12-volt supply. I'm pretty sure there are also 7809, 7812, etc. versions with the last two digits indicating the regulated output.

I wonder how much it would cost them to include those few
pages in QST, especially considering that in those months when there
is no useful material for QEX they wouldn't feel obligated to create
something? I'd be willing to pay more for my membership, maybe as
much as $12/yr more, if such material were in QST. As it is I
sometimes feel that ARRL is paranoid that potential new hams will be
frightend off by any hint that there are technical aspects to the
hobby. I'd like to break down walls between the technical and
non-technical, rather than build up what seems to amount to an
arbitrary division. Or if we must be segragated I'd settle for
receiving QEX in place of QST with my membership, but that doesn't
seem to be an option.

In article <3flogk$3db@cnn.MOTOWN.GE.COM> smiller@motown.ge.com writes:
>Is there still a boatanchors list?

You bet! And it's now automated. Enclosed in the subscription info.

To those of you unfamiliar with mailing lists they work like news-
groups *except* every article goes into the readers'/subscribers' email
boxes, which can number in the hundreds. Thus, you'll want to keep the
content of your article within the charter of the list (and each list
is centered around a very narrow field of interest). For example,
you wouldn't want to post a note to Boatanchors regarding solid
state equipment, nor would you mention operating above 5W on the
QRP list; those would be considered junk mail to all the
subscribers. Once you subscribe to a list the first thing you'll
notice is that there are no flames, and no noise. Remember, what
you say goes into hundreds of email boxes at people's place of
business. Given enough complaints, the list owner can always
unsubscribe a source of noise.

Oh, keep the `unsubscribe' instructions handy; after awhile you
might tire of getting so many emails each day.

Jeff NH6IL

BOATANCHORS CHANGEOVER RELAY GOES "KER-CHUNK"!!!

Greetings and welcome to the new and improved (but still vintage)
"boatanchors" mailing list. An automated list manager should help things
run more smoothly for everyone while still providing the same
outstanding signal-to-noise ratio we have enjoyed since the list's
beginning.
Jack Hill W4PPT has agreed to provide a new home for the list, with the
blessings of Paul Prescott N1AAC who took over from Our Esteemed Founder
Jim Lockwood KM6NK.
NOTE - You need not re-subscribe or take any special action other than noting
the new addresses listed below. The subscription list was moved intact
from the old mit.edu site and you are already on it if you got this message.
Subscribers of the satellite list on boatanchors@beacons.cts.com will also be
moved to this new address.
The new mailing list address is now
boatanchors@ThePorch.com.
Use this now for messages of general interest to the entire group
Please don't use it to subscribe, change address, etc.
The new automated list manager address is

ListProc@ThePorch.com
Use this for subscribing, unsubscribing, getting archived info,
getting the FAQ message, changing your address, etc.
Now send a message to ListProc@ThePorch.com with just
HELP in the body to get info on how to do this.
The new list owner address is
ListOwn@jackatak.ThePorch.com
Use this address only when there is a problem which really
truly can't be resolved otherwise.
Now, yes right now, save this message so you'll have these addresses
handy. Whew, thanks - doesn't that feel better?
You will also soon receive a copy of the "Welcome" message that will be sent
to all new subscribers. It includes more useful info on things like the
purpose of the list, how to subscribe/unsubscribe, etc. It would be a
good idea if you save it along with this message for future reference
or to pass on to interested parties. Thanks.

I built a 15m mobile whip.. From a 4ft tall top loaded CB whip.
A friend gave me the whip, and I was planning on converting it to 10m by
just trimming a little of the wire at the top of the load.
But, I uncoiled about 3 turns off the coil and checked to find out where it
was close to being resonant.. I was shocked to find it nearly resonant on
12 meters.. Then I thought about the fact that the farther up the antenna
the load is, the more inductance you need. I had lowered it down the
antenna but not really affected the coil much, the coil was a tightly wound
22 gauge on about a 1/2 inch fiberglass rod about 8 inches tall.

So I figured, if 3 turns moved it from 11m to 12m, and I had been using the
antenna with about a 3:1 SWR on the lower end of 10M.. it had gone sky high
when I did that. I unwound 3 more turns and found it close to 15M.. I
then trimmed about 1/2 inch off the top and brought it resonant at about
21.300. There are a few problems, the wire is thin and the very top of it
burned off the insulation. And, it bends and moves around easy.. so my
resonant point is always changing.. I'm planning on using something a little
bigger and stronger to make the top stinger out of.. maybe some welding rod
and clamp it to the top with some stainless hose clamps..

I'm gonna be on the look for old 11M top loaded whips to make a 12M and a
17M whip next.

Its Important to use a top loaded whip.. they will have the largest coils
in them.. in this case, my 15M antenna was free.. I've worked JA and CM
on it.. it does pretty good for a 4.5 foot antenna. Althought, you can
probably get a stronger signal with a hamstick or something simalar.. I
was just cheap when I went this route. a hamstick is $20 bucks, so if
you have to pay more then that for your materials, dont. hehe

I saw them at UCLA, unfortunately the copy doesn't contain the
name of what it was copied from. You could try some index
(reports, electronic and/or radio). The articles reference
"Journal of Audio Engineering Society, January 1965" and
"Proceedings of the I R E January 1954" plus some books.

>>Anyway, the point of these articles is that they claim that a
>>flat filter (amplititude) isn't the best, thus the stagger tuning

>>phase response hurt.
>
>Excuse my ignorance but given a bandpass filter how do you tune
>for "linear phase" ?

Linear phase is a specific type of filter, different from
Butterworth or Chebyshev. I would expect that a good filter
design book would cover it. Once you have the right Qs and
loading, you tune all the tuned circuits to the same frequency.

This is easier than stagger tuning! Also it makes it easier to
tune in FM stations since the peak response is when you are on
the stations frequency (no multiple peaks).
```

>certainly appreciate it.

Digi-Key is a large mailorder distributor of electronic parts. If you're into building, you need their catalog. Their phone number is 800-344-4539. That's 800-DIGI-KEY.

I just checked their latest catalog, and the only Stamp they're carrying now is the Basic Stamp. That's a Microchip PIC processor with a built in Basic interpreter, installed on a circuit board with an EEPROM for program storage, and with the oscillator components, power regulator, and terminals for all the I/O pins. The PIC can sink 25 ma on each output pin, so it can drive displays or LEDs directly. The Basic Stamp is $39, and you can get a complete PC based development package, including a Stamp, for $137.99. The raw PIC processor with built in Basic interpreter is $18 quantity one.

The PIC processors, without the Basic interpreter, and in OTP configuration, start at $5.10 each, but the assembler development package, programmer, emulator, and debugger, all PC based, run another $179. A good deal if you're going to be doing more than one of these projects, not so good for a one time project. The bottom line PIC has 13 I/O bits, a RTC, a 16 bit counter/timer, watchdog timer, and the new 71 series also features an A/D converter with a 20 uS conversion time, and a 4 line multiplexer. OTP price for the 71 series starts at $12.30 for quantity one. All the PICs are RISC architecture, and can run at a 25 MHz clock.

These are great little problem solvers, but since you need one or the other development package to get started (sorry, I forgot that bit in the first message), it's not going to be the cheapest way to solve your specific IDer problem.

> So far I've found some ID boards, but they've all been the kind that do
>everything.. from control of the autopatch, to squelch tails and CW ID.

Check with Hamtronics, they have a diode matrix IDer kit that will solve your immediate problem. It's priced at an outrageous $59 though. Their phone number is 716-392-9430. Or look on page 14-8 of the 1992 Handbook

for a 5 chip IDer based on a 2716 EPROM. You'll need access to an EPROM burner to program that. Looks like the PIC isn't that bad a deal after all.

>The controller in the repeater will do all of that, but for some reason,
>it didn't include the ID circuitry. I can't understand that, because I've
>always been under the understanding that even commercial repeaters must
>ID,
>but on 15 minute intervals instead of 10 (as in amatuer). If that is the
>case.. looks like the buisiness I got this from operated illegally!

Probably not. Likely they removed the IDer before selling it to you since it would have their commercial callsign permanently burned in.

>were some "quadrature" beam tube based detectors, but the manual
>doesn't describe it (only ratio detectors and discriminators).

I had started to doubt the information I had on the 6BN6.
Maybe I'll try to post here an ascii schematic of how Fisher FM tuner uses it. As I don't have the service manual yet I don't even know if Fisher used the 6BN6 as a detector.

Thank you for your reply,
john

Oh, I like that. I just looked at the 95 catalog and they have a voice storage board, already built, with enough storage (10 sec) for a voice ID, or even a whistled Morse ID. :-) $39.95.

I think I'll hustle over there and pick up a couple, easiest repeater IDer ever.

Gary

>volts, but it is commonly used to provide 5 volts from a 12-volt supply.
>I'm pretty sure there are also 7809, 7812, etc. versions with the last
>two digits indicating the regulated output.

Paul is generally correct. However, be aware that the 1 amp current
rating represents somthing like a maximum; these chips have foldback
current limiting and thermal shutdown. If you want to run it at 1A,
you need to both heatsink it so the thermal shutdown doesn't kick in,
but you also need to use an input voltage near the minimum differential.

Most of the 78xx devices are spec'ed at something like a 2V input/output
differential. A 5V device will give the most current when regulating a
7V supply, for example. Certainly 7805s are commonly used in 12V powered
equipment, but the output may not give you the 1A mentioned above. I don't
have a data sheet here, but you can probably find a chart of the foldback
characteristic there.

Bill:

Greyhill makes a line of very good optical encoders. They are not
especially cheap (~ $25 ea) but they are top quality. They are also very easy
to use. With an AT&T address you might even be able to get them to sample one
to you.

I forgot to post the answer to the other part of the question.

There are two types of optical encoders. The first is just a "relative" encoder that generates a 90 degree quadrature digital signal. Your hardware (or software) must make sense of what is happening. This is the cheap variety.

The second variety is an absolute encoder. These generate an absolute code corresponding to shaft position. This type tends to be VERY pricey depending on the number of steps per rotation. I haven't used them, but I suspect they come standard as straight binary encoding. For a price you can probably get any coding you want.

0.7uV into 50ohms at 150kHz bandwidth is a noise figure of about 12dB,
so nothing special here.

If you want to improve something like that, you might as well go with a
1dB preamp, rather than a 3dB one, so long as it has good strong-signal
handling performance. Just dont go from a 3dB to a 1dB NF preamp and
expect to see any noticeable improvement.

All my homebrew rigs up through 432 use the MRF955 GaAsfet, because its
cheap, available and easy to use. The fact it gives me a sub-1dB noise
figure is of little importance, except for when I'm on Oscar 13.

Re: GaAsFET preamp retuning
I Perhaps
>the equation doesn't account for the noise generated by placing a very
>large field across a crystal. This can be on the order of KV/cm, due to
>the very tiny gate widths.
>

There will be no difference in electric fields under a gate of a short width (low noise FET) versus a wider gate (power FET) for otherwise identical designs. There will be considerable difference as a function of gate length though. The nomenclature for FET gate dimensions is not what one might expect. The longest dimension of the gate (100 microns or more) is the gate width and the short dimension (on the order of one micron or less) is the gate length.

A low noise MESFET will usually have a single gate feed which usually feeds two gates from the center of a split-source pad design. A power MESFET will have many gate feeds which will require an expensive process step to connect multiple source pads. The mutiple source connection will add parasitic source inductance to the circuit. The number of power MESFETs produced per wafer is small because of the significantly larger size of the device die. Yield also falls with device area. Thus, the devices are expensive to manufacture.

There are many more low noise MESFETs manufactured today than power MESFETs because the demand for low noise satellite dish TV reception in Asia and Europe requires millions of MESFETs per year. I don't know anything about about the small quantity availability of the two different classes of MESFETS, but I would guess that the power MESFETS which are much expensive to produce would be more desirable to sell on the low volume surplus market because of the economics of small quantity/high price versus large quantity/low price. It may be that the more easily available MESFETs are power FETs for this reason. Power MESFETs, however, are inferior in noise figure for every design aspect. It would be well worth one's effort to find out how to get ahold of MESFETs from Anadigics in New Jersey, ITT in VA, Varian Assoc or Watkins Johnson in CA as surplus, or out or spec devices. The real volume producers are Hitachi and Toshiba.

The military and commercial low noise FET world has moved from metal semiconductor field effect transistors (MESFET)s to modulation doped FETs (MODFET)s, also called high electron mobility transistors (HEMT)s, or heterojunction FETs (HFET)s. The very best noise figures come from MODFETS (HEMTS, HFETs etc). I would advise one looking for the top noise performance to find a source of HEMTs for operation at any frequency -

the higher the frequency, the greater the noise figure advantage over MESFETs.

Message-ID: <3fouis$jd6@brtph500.bnr.ca>
Source record: 114634

I designed and built a transverter HF<>2M around the Hamtronics receive converter and transmitting converter. Kit quality was good and instructions fine for the technical kit builder.

I added rf sensed T/R switching, meters for RF out and input current, a 28Mhz amp design as in ARRL handbook, 40dB pad, connectors, relays, and a box. It works great on FM,SSB,CW and Packet. What a blast to build and operate (hearing 2M traffic coming from my old HF rig is strange).

Another thanks to the Homebrew crew for the assistance...

How much physics do you know? Are you interested in a `cookbook'
approach, or are you looking to come up with your model from scratch?

Good books on the subject include:

Moulton, Forest Ray. _An Introduction to Celestial Mechanics_
New York: Macmillan, 1914. No, the date is not a typo;
Moulton's exposition is still unparalleled. Dover
used to have this one in reprint; I don't know if
they still do.

Escobal, Pedro Ramon. _Methods of Orbit Determination._
New York: Wiley, 1965. This one is more adapted to
the computer age, and has some interesting examples of
`Keplermanship.' I understand that it's been reprinted.

Hoots, Felix R., and Ronald L. Roehrich. `Models for Propagation
of NORAD Element Sets.' Spacetrack Report No. 3,
North American Air Defense Command. TS Kelso has
this online on his BBS somewhere; my copy was last
seen in Champaign, Illinois in 1989 or so.

If you're more interested in a cookbook approach, I suggest
copying the C or Fortran code of one of the publicly-available
prediction programs. I speak from personal experience when I say that
it takes a while to get one right, even using a simple model like SGP.

Back seven or eight years ago, I did an orbit predictor based on
SGP that was intended for optical tracking of spacecraft (and
therefore devoted more effort to plotting against star charts than
to characterizing AOS/LOS, Doppler shift, etc.

It still appears to be available from the University of Illinois,
where I worked at the time; you can therefore find some reasonably
commented C code for orbit prediction in the files in the directory

Many years ago, when FETs first became available, I remember reading about some valve (tube in the US) replacements that used FETs, and one or two other components, mounted on standard valve bases. Some people built their own by removing the glass and electrodes, and mounting the FETs etc. in the valve base. I think they generally used something like two 2N3819s in a cascode circuit; this could replace a triode, in most cases, with few if any circuit changes.

As to PCBcad not supporting your Deskjet ... does it support an HP plotter? If so, then there is a shareware ($25) program called PRINTGL which converts plotter commands to PCL. I believe that it would work on any DeskJet (though I have only tried it on the portable 320).

The Jan 95 "The World of Ham Radio" CD-ROM newsletter is now available. This CD-ROM offers more ham programs than any of the others out there! Over 20,000 IBM files for amateur radio are stored on this CD-ROM. Included are the FCC CALLSIGN call book with US & Foreign listings current to 12/94, and AMCALL the new logbook from AmSoft that will auto log from the CD for you. Over 1,350 Radio Modifications. The latest HST, NASA & Space images. Over 700 Megabytes of Amateur Radio Software packed into 1 CD. This CD-ROM is published every 4 months without delay in JAN, MAY, & SEP.

If you would like to get a FREE newsletter about the JAN 1995 AmSoft CD-ROM please send your Internet E-mail address to: amsoft@epix.net

255. Re: Help on Repeater ID'er

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-22 05:22:59 UTC

Regarding a simple CW ID'er: I wish I could give you the exact month/year, but I wrote two articles for 73 Magazine back in the seventies that described CW ID'ers. One used a diode matrix (used roughly 15 diodes for a typical call), and was about 1972. The article was on a "Simple Repeater Controller". The second article, roughly 1980, was entitled "Microprogrammed Sequential Controllers" (or at least, that's the name when I sent it to 73), and described how to do it with a state machine; it used an EPROM and two TTL IC's.
Perhaps you can get the info and a back issue from 73 Magazine.

Which is why the Introduction says:

", have a linear phase charracteristic which extends up to
the 3db cutoff frequency of the filter. Thus, it is
possible to design an FM receiver with a much narrower
bandwidth than would at first seem necessary, which
features the same alternate channel rejection as the set
with the rectangular bandpass filter while at the same
time having stereo separation and high frequency
distortion characteristics which are superior."

I think the reason these aren't see in actual radios is cost.
These linear phase filters would be cheaper than LC non-linear
phase, however most FM receivers now use ceramic filters which
are much cheaper. But probably not as good...

When attempting this sort of thing, does the nature of the dipoles make any
difference, provided they are well connected up with the correct co-ax?
For instance, would scaffolding poles and the conductors from electrical
flex have noticably different effects? Would it be important whether
the rubber insulation was left on?

>the stations frequency (no multiple peaks).

The downside of these filter designs is that they have poor skirt selectivity. That means you can't pull out a distant station when there is a strong local on a nearby channel. Since the FM broadcast band has gotten a lot more crowded since the 1970s, this style of filter is no longer very useful in a high performance receiver.

Ramsey kits aren't great, but it gives you a convenient starting point.
A friend gave me his PA-10 amp after it died for the third time. The
heatsink is minimal, which can be fixed. The output filtering on this
class-C amp is pretty much non-existent, which can be fixed. The
preamp transistor overloads with a mag-mount 1/2 wave in a suburban
location. It's fixed by removing it.

On the other hand you get a ready made PC board, 80-90% of the parts,
and for a extra price, a matching case. Some kits even include the case.
Think of it as a convenient way to get that next project going. Much
easier than buying parts from eight different mail-order suppliers.

I have seen car CD changers that had a many FM stereo transmitter so that you could keep your CD changer safe in your trunk while tuning in to your CD's. I have a car radio (no tape) and a portable CD player. I am sure I could build or buy a small FM stereo transmitter to hook up to the earphone jack of the CD player so I can hear it through the car's speakers. Is there a basic schematic to build this or do I need to order a kit? If so what would be the best kit for this situation?

In the seventees when I had a DRAKE R4A ham band receiver, I tried to replace some of its tubes with solid state circuits. There was an article in some ham magazine (QST?) that I still have a photocopy of to guide me. The results were not really very good. I got a lot more spurious responses etc. and I put the tubes back in. The only solid state mod that I kept was a MC1496 IC for product detection, but that wasn't a tube replacement, if I recall correctly.

If you cannot check the performance of the gear thoroughly after you do the replacement, it may not be worth the trouble.

The W8YY Winter Carnival Special Event Station is being set up for this year. As of now we are planning to operate W8YY for 24 hours straight from Thursday Feb. 2nd until Friday Feb. 3rd. The times will be from 6am Thursday to 6am Friday. The following frequencies will be used: >From 6am to 6pm Thursday, 14.255 Mhz. From 6pm to 11pm Thursday, 7.255 Mhz. From 11pm to 4am Friday, 3.805 Mhz, and the last 2 hour will be held on 7.255 Mhz again. We will also be monitoring 146.58 Mhz during the operation period. Anyone wishing to contact us via Packet can log in on 144.09 Mhz to the MTUBBS. Certificates will be awarded to all stations contacting W8YY during this period. Please send a large self addressed stamped envelope, certificate sized if you don't want any creases. The certificate is 8.5 x 11 inches.

Ok, So the VHF contest was lots of fun except for Sunday evening when lots of the BIG local signals came on at the same time for several hours. Now I know how bad the dynamic range is on my receiver. Splash everywhere. Useless. Anyone got any tips on how to improve things? I run an older Icom 271A. I've known about the poor dynamic range for some time but until last night I was always able to find a spot on the band to work the crowd during the contest. With one or two bigs signals I can null them out with carefull beam headings and carefull timing of when to answer calls. Last night was the one exception. So, has anyone got any suggestions for what I should look at changing in the receiver chain that will help things out? I know the first logical choice is the first amplifier stage but what is the major factor in determining dynamic range? Any suggestions at all will be appreciated. Thanks post here or directly to me via email.

^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^

Hush! Jon Bloom reads this newsgroup! :-) :-)

In my opinion, QEX is one of the better kept secrets of the ARRL. Last September's issue had the USPS statement and it gave circulation at less than 5,000, a shockingly low number.

For those who are interested in subscribing, the masthead gives Cathy Stepina at ARRL HQ as being in charge of QEX circulation and qex@arrl.org as the Internet address. You don't even have to be an ARRL member, except that they charge double if you are not :-) :-).

No connections... just a happy subscriber to QEX.

David, let me suggest that you locate a copy of "Communications Receivers" by Ulrich L. & T.T.N. Bucher (McGraw-Hill, 1988, ISBN 0-07-053570-1) and review the sections on intermodulation, intercept point, dynamic range, etc. It's an excellent reference to have handy while you examine your own receiver's design and hypothesize on how to effect improvements.

Unless, of course, some other poster has some specific insights into your rig in particular.

I might also point out that, at least here in FM19, part of the problem was that at least one of the "big guns" had a *very* trashy signal, while some others were extremely clean by comparison. I would be in favor of a QRO limit during contests; 300 watts might be a nice figure, it puts everyone on a more equal footing and forces operators to focus on things like line loss, antenna configuration, etc., to gain an "edge." But, that's just my opinion.....

Bob-

I don't recall what an HW-99 is, but have had many Heathkits over the years, including an HW-100.

My experience is that drift is "relative"! Until the modern synthesized radios came on the market, with frequencies phase-locked to crystal oscillators, some drift was accepted as a fact of life. Before you embark on a project to completely eliminate your drift, you should reconsider how bad it is.

Most VFOs have temperature-compensation capacitors included in their frequency-determining circuits. Such capacitors are available in both positive and negative temperature coefficients. By trying different TCs, and changing the ratio of compensated to non-compensated capacitance, you can probably improve your drift. (You might also check to see if one of the TC capacitors is too close to a vacuum tube!)

The HW-99 is the CW novice version of the HW-9--runs more power but less bands, if I recall correctly. It probably has the same VFO as the HW-9 QRP rig, which is much more common. I temperature compensated mine, but this is a time consuming process. You can sometimes buy temperature compensating capacitors at Radio Shack--they are often in those bargain packs of ceramic capacitors.

Page 14.20 of the 1995 ARRL Handbook has an oscillaor temperature compensation circuit using two thermisters. More complex, but undoubtedly an easier approach.

When I was a novice in high school, I had an old 2 watt xcvr for CW on 80m.
I used to be psyched to get a contact from NY to Maine.

I used to wonder about how far I could get if I was really high up.

Well, over time, I dropped the ham thing, but pursued the climbing thing.

Turns out I'm heading to Mt Logan in May with some friends.
It's just under 20,000'. 2nd highest in NA, highest in Canada.
(in the area of SE Alaska). Mass-wise, it's a huge mountain.
(and it'll be cold!)

It doesn't see as many people as Mt McKinley.

I was thinking about what radios to bring (CB and weather), and I got
to thinking about my old ham days, and the possiblity of transmitting
from the mtn. (the summit)

I was wondering if anyone would be interested in a project like this.
I don't really have the gear to put together a small, lite QRP cw xcvr,
but maybe someone else would?

The coolest thing would be a mod to an existing
CB unit that could allow it to send/rcv cw on 80 meters.

If someone would be interesting in working together on this,
I'd foot the bill for parts, etc.

The payback? Well, I could send some cool contact cards with a picture
of Logan etc. (sure to be unique?)

ps. In any case, I'm also interested in sources/prices for small solar cells
that could be used to recharge batteries.

> Anybody know of a cheap source for these components?

Cirkit, here in the UK, stock the ALPS Incremental Encoder. It's a simple rotary switch-like device which generates 50 pulses/rev. Maximum speed is 1000 rpm. Two output signals at 90 +/- 45 degrees are produced. They cost #8.18. It requires some electronics to interface it to a synthesiser chip, of course. A PIC 16LC84 processor would be ideal for this. I keep meaning to buy one of these to play with.

> with them.

Steve-

I played with a Nuvistor back in the mid-60s. The feature that they were noted for, was having a very good noise figure, when used as an RF pre-amplifier. Some may have been used as local oscillators, and be useful in QRP transmitters, but I don't recall hearing of them being used that way.

Compared to today's low noise solid state devices, the Nuvistor is probably not so good. However, I would guess the pentodes would have superior intermodulation characteristics, due to the high operating voltages involved.

By the way, do yours have other tube numbers besides 6-52? I recall 4-digit numbers on some, and numbers like 6CW4 on others.

I would just like to say that I agree completely. I liked my first issue
so much I ordered all the back-issues.

Hambrew certainly isn't on the level of Communications Quarterly when it
comes to heavy theory and complex, advanced designs, but they do a great
job of addressing the QRP enthusiast. Constant improvements to existing
designs are presented, and new ideas are discussed for readers to
experiment with.

I have no affiliation to Hambrew magazine, other than I, too, read it
from cover to cover.

The Marantz Model 10-B (one of the finest FM receivers ever, IMHO) used six IF stages each with a three-pole Butterworth filter (18 dB per octave) for a total of 108 dB/octave.

>there is a strong local on a nearby channel. Since the FM broadcast

Listening to many current FM receivers, I'd gladly have a 1960s 10-B instead.

The 10-B wasn't cheap; it sold for $750 in 1966.

Amory Fisher specified the 6CW4 'vistor for local oscillator and
mixer in his top of the line FM-1000 "FM broadcast monitor".
This is a high-mu miniature triode.

Quite a few different ones must have been made. I have the
highly regarded 8393 Nuvistor in a Tek 50MHz o'scope from '64.
If it breaks I'll have a hard time finding a semi that's take it's
place (actually I think there are six of them in there).

I still wonder if the original poster looked at the right numbers
when he identified this tube. I do not remember ever having seen
a "6-52".

Source record: 114594

Hello, All!

Not too sure if this question belongs here or, perhaps, in the
equipment group, but I'll try here first and see what happens...

Anyway, I have heard a little lately about converting old AM/SSB CB
gear to 6m. Note that I said six meters and _not_ ten meters. While I have
not put much thought into this yet, I would think that there would be some
serious problems to overcome in this radical of a change in frequency.

If this could be done, it would be a cheap way to get on 6m, at least
around these parts, since a 40 channel AM/SSB mobile CB can be had for
well under $50!

Anyone have any information and/or comments?

Take Care & 73 de Marty KC6UFM

David,

Your problem is actually twofold:

1. the dynamic range of your RX. Limitation arises in the TX/RX switch
if it is not a relay and in the mixer. You can minimize the latter by
avoiding excessive gain in the front. But you want a good nf at the same
time...

You might be able to find mods for your set, but a better alternative is
to exchange it for a good HF TRX and a good transverter.

2: The splatter by the other stations. Even the best RX wont help here.
Some "contesters" deliberately overdrive their transmitter, to keep
the band around their frequency clear. (I know, they should be dis-
qualified).
What is worse, is that some syntezized VHF multimodes put out a considerable
noise floor, and signals off their frequency, there is little help either.
The bad news is that if I am remembering correctly the 271 is *very*
bad in that respect, like the FT290R.

An example: My RX has a high level FET mixer, but in a contest
I could hear a station with s9+40 and 50KHz down there it was
again loud and clear with s7.

Hope you will be able to solve your problem,

73, Moritz DL5UH

288. RCA NuVistor sub-min valve 6-52

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-24 13:01:55 UTC
From: gsymonds@hpb.hwc.ca
Message-ID: <3g2to4$58k@m.ehd.hwc.ca>
Source record: 114606

There was one nuvistor that was used as a transmitter - it was a tetrode (with a plate cap) used in sonobuoys that output about 600 mw at 80 MHz operating class C. I think it was an 8203. This nuvistor had its shock rating (in g's) specified quite tightly, as I expect it had to survive smacking into the ocean after being dropped from a plane.

Altogether about a dozen types were manufactured, and I know of only two (the one mentioned above and the 7587) that are not triodes. I sold a couple of 6CW4's the other day, and they had a measured Gm of about 14,000.

Recently here in Ottawa, some Communications Electronics surveillance receivers (10 - 300 MHz) came on the surplus market. They use a pailful of nuvistors each - I would guess abot 6 - 6CW4 and 25 - 7587. Virtually all of the tubes (sorry, nuvistors) are low in Gm - they were probably used by a government "surveillance" agency and left on for years at a time.

RCA tried to pretend that nuvistors were not tubes, hence the word "tube" does not appear anywhere in their literature. The name of the RCA "New Vista" television, which used a 6CW4 as an RF amp, is a play on the word "nuvistor"!

: a nice figure, it puts everyone on a more equal footing and forces
: operators to focus on things like line loss, antenna configuration,
: etc., to gain an "edge." But, that's just my opinion.....

I have to disagree, even though I'm a pretty experienced QRP
VHF+ contester.

The problem with the limit is that it is likely to encourage people
to run solid state bricks flat out, as opposed to tube amplifiers
loafing around. The trashy signals usually result from high power
bipolar finals run at maximum output on the meter. The problem isn't
the 3rd order IMD, it is really the high order stuff. Mark Wilson,
AA2Z, got excellent results running a 28 volt FET driver between his
transverter and the tube final. I think W2SZ/1 now does this as well.
With a well designed circuit, best signal quality often occurs when you
run a brick at 1/2 the maximum output. Not sure how to run those bricks
with poor bias circuits (those that don't even have a monotonic gain vs
output curve). However, you might as well run those hybrid modules at
full rated output--lowering the output doesn't help much.

**********************************************************************
From: dyeske@st6000.sct.edu (David Paul Yeske)
Subject: CD changer FM transmitter

I have seen car CD changers that had a many FM stereo transmitter so that
you could keep your CD changer safe in your trunk while tuning in to your
CD's. I have a car radio (no tape) and a portable CD player. I am sure
I could build or buy a small FM stereo transmitter to hook up to the
earphone jack of the CD player so I can hear it through the car's
speakers. Is there a basic schematic to build this or do I need to order
a kit? If so what would be the best kit for this situation?
**********************************************************************

David:

Don't bother trying to make one. Radio shack sells a complete one for
about $30 to $40. It is MUCH easier than trying to build your own.

If you are just interested in building one for the thrill of building
it, it is not terribly difficult to build a discreet component stereo
transmitter. I am not aware of an off the shelf stereo tranmitter IC. If there
was one then there would be no challenge in building it anyway.

The blocks needed to build on are a 38 KHz oscillator, a divide by two
circuit and filter for the 19 KHz pilot tone, a double balanced mixer, and
circuitry to generate a Left minus Right audio signal. This stuff generates the
stuff for the stereo part. Then you need a FM transmitter (a VCO of some sort).

If you are interested in further information please ask.

The weakest link(s) are usually the mixers. Thus, if you can switch out
the RF amplifier in the radio this will help a lot--have a single mast
mounted preamp feeding the bpf/mixer. Alternately, you could improve
the mixer--Mutek electronics once sold conversion boards for Icom receivers.
These were a relay for low loss T/R switching, a low noise preamp, and a
diode passive mixer. A mast mounted preamplifier accomplishes the
first two even more effectively.

I've been collecting parts data, mostly RF parts data and utilities
for many months, and I've put them on my computer. They are now
available by anonymous FTP (or available via mosaic's ftp interface...
more on that later) for now. If things go well, this availability
will continue.

I have two requests:
1) please ftp the files between 7 am and 11 pm, the computer is
in my dorm room, and the drive is loud.
2) Please contribute!!

More on Item 2: If you have any parts data on RF transistors, diodes,
anything, please let me know, and I'll add it to the archive. Also,
if you have any free software/utilities relating to RF circuit design,
the same applies.

I have the following:

-Motorola RF data (which rev I'm not sure), noise and s
parameter data files that they provide on disk.
- NEC RF data (same as above) and plotting/selection utilities
(from the wireless sampler I won at packrats this year)
- HP parts data (and hp appcad in the software directory) that came
with hp app-cad

- some spice models for op-amps and such

That's it, so if you know where I can get more, please let me know!

Here's the addr: lancedude.stu.rpi.edu

The directory structure is a little Kooky, here's a summary

pub/Stuff/Electronics
pub/Stuff/Electronics/Data
pub/Stuff/Electronics/Data/RF_DATA
pub/Stuff/Electronics/Data/RF_DATA/moto
pub/Stuff/Electronics/Data/RF_DATA/nec_si
pub/Stuff/Electronics/Data/RF_DATA/nec_gaas
pub/Stuff/Electronics/Data/RF_DATA/HP

there's lots more there... poke around and find out for yourself

You can also get to lancedude through my www home page at rpi,
there's an FTP link to lancedude there (addr is in my sig).

73 and good luck,
de WS2B

Well the thing that worked for me was the Mutek front end replacement board. It gave a remarkably better noise figure and 3rd order intercept than the stock unit. It has a reed relay TR replacing the stock PIN diodes, the RF stage, a SBL-1 diode ring first mixer, and a post mixer amplifier on it. This board is no longer produced, but the fact that it solves most of the problems of the radio, aside from the phase noise of the LO, should point you in the right direction. I suspect that the relay is the key to the better noise figure and that the first mixer is the key to reduced IMD. Certainly the new RF stage is nothing fancy, just a bipolar amplifier. I didn't have the option to try changing one circuit at a time with the Mutek board swap.

Gary

Actually Rob, this is not a problem. The VCO will not lock at that frequency. Although whoever sold you the radio said it would transmit up there, I'm sure Yaseu would never admit that. I did mods on many FT-530's and got so many questions about the TX range, I finally tested one and found that it will indeed transmit to 470 mhz, but the power output drops to milliwatts. The transmitter has a tight passband for the amateur band, and power drops off exponentially outside the band. I should add my discalimer that the radio is not type accepted for operation outside the amateur band. Since I no longer work for Radio City,(quit to go to college) though, I say... Knock yourself out!

Jim N0WMR x - amateur radio tech.
: Make sure you don't have any repeater offset turned on. A little
: experimentation with an FT-530 around here shows that it does transmit,

Add my opinion to the pot - QEX is WELL worth the $12 a year to subscribe. Unfortunately, sending the thing over the border doubles the cost. So, if you are living in the US, I wouldn't be griping too much about the extra cost. Just remember, it could be worse!

ri> may know... Generally, Anything.

There is a program called PCTRACE5.ZIP or PCTRACES.ZIP. It is shareware, but I don't know if it is still supported. The support BBS listed in the documentation no longer exsist. This copy is over two years old but works great. It will create double sided printed circuit board traces. You identify the parts and connections.

Not all parts have board layouts but the program has the ability to allow you to create new parts layouts (i.e. I had to create a three point trace layout for a transistor, was not a big problem)
You also place the parts in a layout on the board and it draws the connections. By moving the parts around the board you can change the level of success with all of the connections being done on the circuit board and not having to wire any connections. It will print out the layout on several printers. I had to use the HP lazerjet 2 setting and it printed fine on my HP lazerjet 4.

All Electronics Corp. catalog (800-826-5432) sells "Press-N-Peel" by Technick or "Toner Transfer System" by DyanArt Designs. I have not gotten to this point yet because I just discovered PCTRACE. It appears that you can use Lazerjet or copier to transfer the design to a special paper in one of these kits. The paper is attached to the copper clad board and then etched. The only thing left is to drill holes and solder.

Good Luck.

>it but the guy who gave it to me, told that it is a USA made amplifier.
>The only inormation about the amplifier on its box is its model which
>says TX500. It contains four Toshiba power transistors. I was wondering

uhuh...I bet..the "TX500" identifies it as a "Texas Star 500", this is a
cheap brand of transistorized linear that some bunch of Criminal-Banders
makes in a garage somewhere...supposidly in Texas. The transistors are
similar to the Motorola MRF455-454 types and the literal output RMS is
seldom over 250 watts. The "500" probably means input, or "CB-good-buddy
watts" or something.

Forget returning it to 'the Factory' for service...they move every weekend
or so Im told! The amp isnt worth much. A matched set of MRF455's is $90
so it might cost you $180 to fix it in parts....and then there's the small
matter of it's spectral purity...heh heh...do us all a favor OM, throw the
bastard in the junk box and BUILD yourself a good amp...one with some real
tuned circuits so it dosent splatter and distort. It's easy to do, just look
at the design that the ARRL Handbook pubs...or get one of the kits from
the dealers in QST. A transistor amp *CAN* be clean...but the TX500, like
99% of the CB amps isnt and cant be made clean easily.

302. Stepper Motor: Useful?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-24 21:08:09 UTC
From: R0264@info.onet.edu
Message-ID: <17330E2E9S86.R0264@info.onet.edu>
Source record: 114597

I have 3 or 4 (I think) little stepper motors that came out of Teac floppy disk drives -- the motors used for head positioning. I wonder if they might work to remotely turn an air variable capacitor in a tuning circuit at the feedpoint of an antenna. I don't know how to use them though, and wonder if anyone does. There are 6 wires: brown, brown, yellow, red, blue, and white. The shaft seems to be about 1/8" or 3/16" (probably metric). The motors are nearly cubical in shape, about 1.75" x 1.75" x 1.75". The label on one says Teac 3Z13B, and another one says Teac 5X03.

I also have 4 bigger ones with worm gear shafts that came out of old 8" floppy drives, also for head positioning, I think. These are cylindrical, about 2" in diameter and 3" long. The worm shaft is about 3/8 to 1/2" diameter and about 5" long. These have 4 wires: black, brown, red, and orange, not necessarily in that order. The label says Warner Electic No. SM-024-0045-AS, then RES/0 19 Ohm, then RATED 1.26 AMP- 24VDC, and some other numbers that I can report if they mean anything to anyone. I don't know how to use these either.

I'd appreciate any info on these, how to use them, and ideas on how they might be used for amateur radio operations. TIA.
---Phil Emerson, AA8JO.

>unknown Marine; Khe Sahn, Viet Nam

Well Carl, I'm glad you had a good experience with Ramsey. Having built several Heathkits in my day, and two Ramsey kits, I'd say there is a big difference between what *was* at Heath and what *is* at Ramsey. Granted, Heath wasn't perfect, but I had 'high manufacturing yield' with Heaths, and received good post-sales service. The designs were mostly pretty reasonable and reliable. The two Ramsey kits I built were supplied with bottom-of-the-line components, and both had missing parts that I had to scrounge from the local parts emporiums. (It wasn't worth the hassle and the stamps to nag Ramsey). The designs (for the kits I built) are marginal, and though I got them to work, I suspect less experience builders might run a high risk of being disappointed. Kit designers face a big challenge in the area of manufacturing yield, since they have zero control over the 'factory'. Heath took pains to address the issue. Ramsey, in my limited experience of two inexpensive kits, does not.

Don't get me wrong, I don't mean this to be a 'trash Ramsey' post. They were low cost kits, and I did enjoy building them. But I would not have been a happy camper (or solderer) if I had paid any more for what I got.

73, Dave NG0X

P.S. Regarding English translations: ooooooohhh what a hot button of mine you just hit! It pi**es me off to no end to spend $1800 for a new radio and see things like "moduration input" and the like in dozens of places in the manual. There is absolutely NO EXCUSE (rude shouting intended) for that stuff from a multi-national manufacturer. I'd love to build up enough frequent flyer miles that I could go over to Japan and personally slap someone silly over the stupid errors in their documentation. Unfortunatly, that would probably also be considered rude. :-)

304. How to get 1:1 SWR on 5/8 antenna?

Yep, we do. The IPA consists of an MRF-148 driving an MRF-150 (then
driving the 8877). This lineup easily does >100 watts, but we run it
between 40-60 watts. The bias was optimized for good 3rd and 5th
order IMD (I forgot the numbers). This seems to agree with what zack
was saying.... run the lineup below the limits... and you're bound to
get good IMD performance (of course FETs are better in some ways to
start with).

What we offer on the Internet is "A FREE HAM NEWSLETTER" and nothing
more. The purpose of the newsletter is to inform the interested
Amateur Radio public that our product will provide them with useful
information about the hobby of Amateur Radio. The decision for
another individual on the Internet to receive a NEWSLETTER is the
readers decision, not yours. My post gives the reader the choice
if they wish to continue by requesting our newsletter. In the case
of yourself, you did not need to respond.

The ease of posting Usenet News articles causes many inappropriate
articles to be sent to the network.
An article can be inappropriate if it:

-- Is devoid of useful information or ideas.
-- Is sent to inappropriate newsgroup(s).
-- Is really intended for a particular individual,
rather than the entire Usenet community.
-- Contains rude or insulting remarks.

Articles should be composed thoughtfully. Consider sending an
electronic mail message rather than posting an article, if
appropriate. Be aware of the fact that many sites must pay long-
distance telephone charges to receive your article. Also be aware

of the fact that some of the popular newsgroups have tens of thousands of readers. 10,000 people each reading your article for 20 seconds spend a total of 55 hours reading your article. At the end of most articles there is usually a small blurb called a signature or sig. This usually comes from a file in the person's login directory and is appended automatically to the message by the news reader. Some people get carried away with their signature and place complex ASCII drawings or cute sayings at the bottom of their messages. These signatures bother most people and it is considered poor "netiquette" to ave signatures larger than about 4 lines. Please remember to save your signature file as plain ASCII text, since vendor dependent binary files (such as Microsoft Word files) are not portable across the entire Internet community.

Many new users wish to test their ability to post before they actually say anything of any interest to anyone. Don't post test type messages to an active newsgroup. This will interrupt quite a number of people and is considered poor "netiquette". There are usually a number of "Test" newsgroups (they usually have the word "TEST" in their name) that can be used to verify that posting from your host will be successful. Some test newsgroups (like ALT.TEST) have automatic E-Mail responding software. A post to those groups will cause electronic mail from all over the world to be sent back to you as your post gets forwarded from site to site.

The "Newsgroups:" line in a news header isn't limited to just one group. If a note makes sense to more than one area you can cross-post it to other newsgroups by just separating the newsgroups with a comma on the Newsgroups line. It is considered poor "netiquette" to cross-post to more than several newsgroups.

When posting new articles to News, please remember that News runs on many different hosts and operating systems. The majority of posts from the Usenet are viewed by people running non-DOS/Windows operating systems. Inserting graphics or non ASCII text (such as different fonts, underlining, color changes etc.) in an article will appear as unintelligible garbage to almost everyone else. When responding to articles, use the Follow-up Article option instead of the New Post option. This will maintain a reference link between your message and the article you were reading at the time of your posting. People reading your message from other "thread based" news readers, will be able to understand how your message fits into the rest of the conversation. Intersperse your comments between the quoted text and delete any large quoted sections that do not pertain to your response. Someone can always find the original text by clicking on the unique Message ID. Also, use Message ID's when referring to other articles and never refer to another article by it's article number. Article Numbers are never the same from system to system so only people reading news on your own local system will know to which article you are referring.

Try to keep your text in a generic format. Many (if not most) of the people reading Usenet do so from 80 column terminals or from work-stations with 80 column terminal windows. Try to keep your lines of text to less than 80 characters for optimal readability. If people quote part of your article in a follow-up, each line gets indented a few characters and gets proceeded with a ">". Thus, standard lines of 75 characters or less are best for later readability. Be careful when using proportional style fonts since they allow you to place more characters per line than fixed style fonts.

Last but not least BOB, your suggestion that persons should be asked to CRASH MAILERS WITH ELECTRONIC FECAL MATTER will be met with a strong challenge here at EPIX.NET!
Should such an occourence happen we will refer the matter directly to your commander, you are under the Uniform Code of Military Justice!
Furthermore any damages caused by your suggestion will be dealt with in a court of Civil Law.

Hi Marty... This CAN be done on only 1 model of 40 channel SSB chassis
(that I'm aware of) ..the Cybernet using the PLL02A phase locked loop.
There were many marketed models using this chassis including Colt,
Citizen, Hygain... I have done it to 2 radios and it DOES work !

The mixing scheme used in this chassis is what lends itself to the
possibility of conversion to 6 meters... the difference of 37 Mhz and
10 Mhz (rounded off) puts you into the CB band around 27 Mhz.
By using the SUM instead of the difference of the mixer by changing the
filtering on the output of the mixer, you'll end up on roughly 47ish
Mhz. A crystal change will bump you up into the 6 meter (50 Mhz) band.
The mixing goes on at the first mixer of the receiver and final mixer in
the transmitter stage, therefore, the front-end of the RX and the PA strip
of the TX beyond the mixer must be changed to work at 50 Mhz.
This involves removing, modifying and replacing coils, transformers and
capacitors.
I would caution anyone without a pretty thorough knowledge of electronics
and full understanding of the mod notes NOT to attempt this it.
Removal of the coils for the mixing filter, front-end and TX strip
and reworking them can be a frustrating endeavor. Then comes the

substitution of capacitors and tuning of the reworked coils and
transformers...and removal if more turns are required to be taken off or
rewinding the coils if you had taken too many turns off ...ughh !
I think you get the picture ! If you don't have the experience or the
patience, you WILL end up with a basket case CB radio.
There are some idiosyncrasies about the mod even once it's done...
some of the channels get mixed up depending on what mode you are
using...ie.. channel 10 on USB will not be channel 10 on AM or LSB.
This is due to the change in the mixing (sum instead of the difference).
Give it a try if you have confidence and time and don't mind the
possibility of getting frustrated halfway through...All you will be out
is $50 for an old CB and a bit of your time.
As I said, I did it twice and it DOES work.

You could use them in an ATU turning the capacitors and coil.
-however a application where DC motors with reduction (200-500:1)
in an ATU is used will be cheaper and a much simple design/control unit.

Our Swedish ham.magz - QTC, had two articles recently on both stepper and
DC motors. They where both homebrewed designs.

Hi, everyone !!

I'm Paulo, from Portugal. I wanted to know if someone
could help me...

I want to be ham, and all it takes to it is to take
an exam. But I also want to build my own equipment !

So, I'm asking you if you could tell me (or send me, if
it is possible) where I can find some schematics (with
PCB drawings included, if possible) of xmtrs and receivers
for the 2m band .

If you can help me, please e-mail me !!

Thanks for everything and I hope to ear from
you soon

Hello,

Here is a remarkably simple (and probably dumb) question from a total neophyte
who is just getting his feet wet in building a QRP CW transmitter:

When you use a Dip meter to tune an L-C circuit, does RF energy have to be
present for the needle to 'dip'??

Embarrassingly yours,
Andy, VE7 HIP (quiet as hell)

Subject: Stepper Motor: Useful?

I have 3 or 4 (I think) little stepper motors that came out of Teac
floppy disk drives -- the motors used for head positioning. I wonder
if they might work to remotely turn an air variable capacitor in
a tuning circuit at the feedpoint of an antenna. I don't know
how to use them though, and wonder if anyone does. There are 6
wires: brown, brown, yellow, red, blue, and white. The shaft seems
to be about 1/8" or 3/16" (probably metric). The motors are
nearly cubical in shape, about 1.75" x 1.75" x 1.75". The label
on one says Teac 3Z13B, and another one says Teac 5X03.

I also have 4 bigger ones with worm gear shafts that came out of
old 8" floppy drives, also for head positioning, I think. These
are cylindrical, about 2" in diameter and 3" long. The worm
shaft is about 3/8 to 1/2" diameter and about 5" long. These have
4 wires: black, brown, red, and orange, not necessarily in that
order. The label says Warner Electic No. SM-024-0045-AS, then
RES/0 19 Ohm, then RATED 1.26 AMP- 24VDC, and some other numbers
that I can report if they mean anything to anyone. I don't know
how to use these either.

I'd appreciate any info on these, how to use them, and ideas on
how they might be used for amateur radio operations. TIA.
---Phil Emerson, AA8JO.
****

Phil:

In the case of the Teac motors, they sound like they came from old 5 1/4
inch disk drives. These SHOULD work for fairly low torque applications driving
capacitors. You need to generate a 90 degree DIGITAL waveform (at 12 volts
however!) to drive the 2 coils inside of them. When I get a chance, I may be
able to scan in the schematic used by the IBM PC (remember the original with a
cassete port and no hard drive) for their floppy drive. The circuit is
basically the same in all floppy drives.

In order to get more torque, you could couple the motor to a small gear
train. The nice thing about stepper motors is that you can drive them REALLY
slowly. They have an upper speed limit but there is no limit to how slow they
will go. Another useful feature is that if you hold the digital phase constant
with power applied they make really good brakes.

The ones out of the 8 inch drives sound like you ought to be able to
rotate a battleship (or at least a small sloop) with them. They were designed

to run off 24 volts just as the label says.

One additional VERY important piece of information is that they should NOT be driven directly by the rated voltage from a low impedance source at low speeds. Low-tech drivers for steppers usually have a series current limiting resistor so you don't burn out the windings at low speeds.

If you need more info, send me an e-mail.

: and if so, what was thr solution?

I am not familiar with this particular radio, but one additional way to improve temperature stability is to regulate the temperature around the VFO. Use a small heater just like they do in crystal ovens. Build the circuit to regulate the temperature around 100 degrees F. It may STILL go out of control when the ambient goes above 90 degrees or so, but it will be a lot less drift than starting from room temperature. An additional benefit is that it should stabilize more quickly, since you are intentionally adding more heat at the beginning. The down side is that running it hotter will make the VFO have slightly more noise. I'm not sure what effect that might have in this radio. Maybe Zack has some thoughts on this.

john-

Yes, I was referring to the linear range compared to that of a device working off of a lower voltage (12 volts) power supply.

You might guess I don't really know what I'm talking about! A signal of the same power level, but in a different impedance, would be equivalent. I don't know how the intermodulation characteristics of a Nuvistor's higher voltage/lower current compare to those of a solid state device with lower voltage/higher current. Then, how do noise figures compare for such devices with equivalent intermodulation characteristics?

Best place to start looking is Allegro Semiconductor.
They make UCN-5804 drivers for the 6 wire steppers. I also
have an app-note in Signetics 8051 microcontroller data book
using steppers.

>shaft is about 3/8 to 1/2" diameter and about 5" long. These have
>4 wires: black, brown, red, and orange, not necessarily in that
4 wire steppers are a little trickier since I believe
there are no 1-chip solutions for driving them. I believe 2 chips
will drive 'em tho'. Once again, Allegro has the chips. It used
to be called Sprague Semi but they were bought out.

>present for the needle to 'dip'??

You can use a dip meter in two ways. On an unenergized circuit the dip meter itself generates the RF (just a simple oscillator) and the "dip" of the meter happens as you tune either circuit (DM oscillator or circuit under test) to the frequency of the other and the CUT absorbs some of the oscillator output. You can do the reverse also, with an energized circuit and the DM oscillator off, allowing the DM circuit to absorb some of the CUT energy, in which case the meter will peak on resonance instead of dip. In either case you have to have the two circuits close enough to couple the energy, but if you get them too close the reading becomes unnecessarily broad from too much loading.
>

>a kit? If so what would be the best kit for this situation?
>
>
David:
You can try building the Ramsey Stereo transmitter. They have a crystal
controled pilot that has really cleaned up the unit. I have built two of
these units and they do work well. You will probably have to add aditional
filtering on the power supply leads to the transmitter to filter out any
aditional vehicle induced noise but should be stable enough for this effort.
Note:
I have seen some of the CD players going for less than the Ramsey kit price.
You may be ahead if you consider one of these units as far as price goes.
I have also seen a design for a fm transmitter using a BA 1404 (which is what
the Ramsey uses) in a past issue of Radio Electronics but cannot remember the
month and year of the issue, comments anyone??

From: dugan@ginger.biophys.upenn.edu
Message-ID: <3g70mi$iqo@netnews.upenn.edu>
Source record: 114527

Can anyone offer pointers about using vacuum tubes to switch very high voltages? I have a possible application to switch 30kV on and off at a 500 Hz rate, with a 20mA load.
I have looked into using relays for this, but they have several limitations (lifetime and switching speed being foremost).

I'm looking for either tips or suggestions for good references on the subject.

Thanks.

Ben Dugan (dugan@ginger.biophys.upenn.edu)

I find your (AMSOFT) reply as innappropriate, perhaps more innappropriate, than Bob's comments, and a substantial waste of "bandwidth".

Perhaps what Bob should have said is that it is contrary to Internet's policy for Internet to be used as a vehicle for commercial advertisement. That is a fact. While I can not say that the policy is a legally binding one (that is for others to say), it certainly is followed by the vast majority of commercial enterprises, and for good reason. They realize that they run the risk of alienating potential customers who may not appreciate such a blatant disregard for net etiquette and policy. Like Bob. And like me. Mind you, it is no big deal to me personally. But I don't like advertising here either, and there are plenty of alternatives to AMSOFT.

You seem to be aware of some internet policy judging from your long quoted (though not attributed) "lesson" to Bob. Perhaps you would find a more complete review of policy personally enlightening as well as commercially "prudent".

I enjoy working 80 meters AM with a Hallicrafters HT-37, going through a Globe LH-1 linear amp. I am pushing about 120 watts. Unfortunately although I am being told I have a good strong carrier, at times I have very little modulation. I own an older model oscilloscope (Hickok Wide Band Model 677) and would like to monitor my transmission with it to check my modulation. Can someone pass on some instructions on how to do this. By the way I'm using a MFJ-901B antenna tuner after the Globe linear to an 80 metter dipole. My E-Mail address is Radio@postoffice.ptd.net . Any help would be greatly appreciated.

Ramsey's FM-10 kit is probably what you're looking for. I've built two of them, one for myself and one for a non-techie friend, and they are pretty decent little transmitters. They're stereo, have reasonably good audio when run from batteries or a good DC supply, and they're easy to build.

JDR Microdevices sells another FM stereo transmitter, but I'm not familiar with it. They also sell the Ramsey kit (though they don't identify it as such in the catalog). You can order them, or get their "Electronic Components" catalog, by calling (800) 538-5000.

>present for the needle to 'dip'??

Yes, the RF energy generated by the *dip meter* has to be present. The circuit under test should be "cold", IE no power applied. A "dip meter" (they used to be called "grid dip meters" when tubes were used) is a tunable oscillator. Some of the power of the oscillator is coupled to the circuit being "dipped". What the meter is measuring is a change in the current of the intrument's oscillator when it's coupled to a resonant circuit. The looser the coupling, the sharper the dip. A close coupling will "load" the LC circuit and broaden the dip.

>MFJ-901B antenna tuner after the Globe linear to an 80 metter dipole.

Ok, to measure modulation, you want to set the scope up to display
a trapezoidal pattern. To do that, you need to couple the vertical
display to a sample of your RF output, and the horizontal display
to a sample of the audio modulation, IE the scope needs to be able
to do a XY display. What you'll see under modulation (with a test
tone) is a trapezoid that's tending toward a point as the waveform
goes to the right of the scope. You're at 100% modulation when the
trapezoid's right edge just comes to a point, forming a triangle.

With speech input, the trapezoid will "dance" back and forth with
the amplitude of the speech. Again, if the trapezoid just comes to
a point on speech peaks, you're at 100% peak modulation. You don't
want the trapezoid to come to a point before it reaches the right
edge of the horizontal sweep. If it does, you're overmodulating.
The setup looks roughly like this.

```
.001 uf
RF sample<-----||---------->scope vertical

1.0 uf
AF sample<-----||---------->scope horizontal
```

If you just want to look at your modulation envelope in the time
domain, just insert a sampling diode in the sample line from the
transmitter RF output, use a RC low pass filter on the diode output,
and observe the speech waveform with the horizontal timebase set
to an appropriate sweep rate. You want to see a clean envelope with
no clipping. A suitable sampler circuit is shown below.

```
001uf 1N34 10k
RF sample<-||----->|---x--/\/\/\/-------> to scope vertical
|
= .01 uf
|
GND
```

The UCN5804 is nice for unipolar (6-wire) motors. See my optoisolated
driver (pc_stepr.tar.Z) and 3 axis controller (3axis.tar.Z) on the circuit
cookbook site. PCB layouts, schematics, and instructions are included.

SGS-Thomsen makes the L297 which does bipolar (4-wire) steppers. I think
up to 600 ma. Paired with the L298, it becomes a chopper drive capable of
up to 2A. I've got a 90% finished design for these.

From: negaard@draagen.graceland.edu
Message-ID: <NEGAARD.95Jan26191427@draagen.graceland.edu>
Source record: 114537

I'm a brand-new, over-enthusiastic amateur, with lots of desire and
almost (!) no money. What I'm interested in is a project that will
allow me to build a modular multi-mode transceiver. Does anyone know
of a design, or even just a starting point?

I've eleven years of experience as an electronic technician, and took
the 2M (miniature and micro-miniature repair) class while in the Navy,
so I'm confident of my ability to build, and maybe even design (with
modern solid-state, it's almost black-box, anyway!)

What I really need to know is, "where should I be looking?"

Any response would be appreciated.

There is a triode HV regulator that used to be used in color television sets.
The tube type escapes me but it should easily handle 30 kV and 20 mA.
You need a tube data book to look it up. Maybe someone else can remember
better than I.

Hi Kevin,

I like you idea, so a few thoughts. I am not quite sure that
the high mountain will be of much advantage on 80.
Maybe you should still think how to get the ant well off the
ground. I am currently also working on the idea of low band
portable operation. Look int kites.

>The coolest thing would be a mod to an existing
>CB unit that could allow it to send/rcv cw on 80 meters.

Does not sound a good idea to me. You would have to rebuild most of it.

>ps. In any case, I'm also interested in sources/prices for small solar cells
>that could be used to recharge batteries.

On this I can give you the following advice:
The panel should have a higher power rating than the radio.
so a 10 W with an output voltage of 18V might be OK to
charge a 12 V battery.

Get it from a reputed manufacturer or dealer, there are lots of dodgy
solar panels around, which might deliver only 1/10 or so of their
rated output.

73, good luck, Moritz DL5UH

340. Q: Curious circuitry inside a Radio Shack antenna preamp.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-27 18:11:53 UTC
From: CC015012@brownvm.brown.edu
Message-ID: <3gbd0q$26b@cat.cis.Brown.EDU>
Source record: 114540

Hi,

I have an antenna preamp that I got for cheap long time ago at
Radio Shack. It might have been broken. I've just started
looking at it. It's a two transistor thing with 14dB gain it
says.

I'm treating this project first and foremost as an educational
endeavour.

I haven't found any info on the two bjt's: BFT97 and BFA96.
I wonder if anyone has the NF on these.

I think the first one is fine but I am worried about the second.
As it is, Radio Shack runs it with near 90mA current and close
to 8 volts accross it (at Vcc = 12 V). It gets unbearably hot.
With Vcc equal to 9 Volts things cool down a bit.

The first stage is biased by a 10k/10k voltage divider, feeding the
base of of the grounded emitter bjt. Output is taken at the
collector/RFC_1 and AC coupled to the next stage. Now there is
what I assume to be a negative feedback around the cb junction:
a 1000pF in series with 820 ohms. My shaky analysis tells me that
with a 75 ohms source impedance this stage is capable of a gain of
820/75 or in excess of 20dB which doesn't rhyme with the stated
14dB *overall* gain as the next stage has gain too:

Stage two has a 1k/1k divider to bias the base of bjt_2 to Vcc/2.
The transistor is in a common emitter configuration
with a emitter degeneration resistor of 47 ohms bypassed with
what appears to be a 2pF chip capacitor.
But there is a 1000pF capacitor from the base of bjt_2
to Vcc. This must be in error as it grounds the input to the
second stage.
I tried unsoldering it even with a tuner I couldn't tell things
changed for the "better" (I could be overloading the tuner -
I don't know yet) .

Gain is developed over another RFC, RFC_2 from Vcc to the collector
of the 2nd bjt. It is puzzling to me however that the circuit
which I speculate do a bit of negative feedback (an RC accross the base
-collector terminals) here consists of 1000pF but now with a resistor
of only 75 ohms. See, if my thinking is correct that with this negative
feedback the gain of the stage is R_feedback/R_source, then the
gain of the second stage approximates 75/Z_rfc_1 which could
be very small. I just realized that I probably look at

this using Spice but I'm not sure about how to set the bjt parameters for RF devices.

So, my final question is, why didn't Radio Shack just use the last bjt as an emitter follower ?

thanks,
john 015

341. Crowbars for 3kV supplies?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-28 00:16:46 UTC
From: G3SEK@ifwtech.demon.co.uk
Message-ID: <829089796wnr@ifwtech.demon.co.uk>
Source record: 114542

I'm planning to build a 'crowbar' switch that will dump the charge
from a 30uF 3kV capacitor in the event of a flashover in the PA.

This is required by the spec for certain Siemens transmitting tubes.
To safeguard the tube, the HV power supply must be capable of being
short-circuited by about an inch of 0.12mm wire (yes, 36 AWG) without
blowing the wire!

How do they do that, in commercial transmitters?

OE5JFL has published a circuit that is triggered from the fast rising
edge and does two things: turns off a solid-state relay in the AC
power feed; and it 'crowbars' a string of thyristors across
the HV rail.

It does work - I've seen it in OE5JFL's shack and others have
reproduced it. As an alternative to opto-triggering three or four
1200V thyristors in series, is there a source of relatively
inexpensive thyristors rated to 3-4kV? The device only needs to be
rated to handle about 10A continuous, because there's a series
inductor to limit dI/dt and take the 'sting' out of the current
transient.

In days of old it would no doubt have been done by a large glass
something-tron, but I'd prefer a compact solid-state solution.

Any ideas, please?

Source record: 114543

I've got the original version and am very happy with it. The feature of using CW commands to control it is unique and makes operation fairly simple. I'm not an avid contester, but the ability to create custom messages (into which you can insert characters on the fly) and to generate serial numbers makes it well worth the price. It was about $50 originally for just the board and uP.

From: ianc@werple.mira.net.au
Message-ID: <3gd08r$7do@werple.mira.net.au>
Source record: 114544

I am currently playing around with building a transmitter using
a pair of BUZ-71s in push pull in the output. So far I have popped
a couple for different reasons. Both went short circuit drain to
source.
Are there different conditions that will make a power MOSFET
go open or short? I think my failures were due to
1) excessive current (MOSFET turned on and only DC resistance
primary of output transformer)
2)excessive Drain - source voltage (lead to dummy load fell off
with resulting odd impedance reflected back through lo pass filter)

Will execessive gate voltage, for instance, cause a failure that is
a permananet O/C or are all power MOSFET failures S/C?

From: ianc@werple.mira.net.au
Message-ID: <3gd0hu$7mc@werple.mira.net.au>
Source record: 114545

I am building a transmitter using a pair of BUZ71 Power MOSFETS in
push pull into a 'conventoinal' broadband transformer.
Initially I was using 4 Amidon FT-50B-43 Toroids for the transformer
but some calculations show that these cores may not be up to
100 Watts CW at 1.8Mhz.
Has anyone used powdered iron toroids for broadband output
transformers?
The extra number of turns required to achchive minimum inductance
will reduce the flux density and improve the loss of the transformer
core, but will they increase losses due to their own extra resistance?
My rough calculations show I would need about 35 turns on the 50 ohm
side of a transformer using T-106-2 core.

Is this is worth persuing or should I stick to increasing the size of
the ferrite core?

I'm looking for a book that explains how to make unusual (or not sold)
electronic gadgets.

Any titles suggested?

347. Sources for RF Parts?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-28 12:07:29 UTC
From: system@hale.cts.com
Message-ID: <7u1mZc2w165w@hale.cts.com>
Source record: 114548

I get RF Parts Co. catalog, butthey don't stock alot of things I'm after for my projects. Does anyone else have information on similar companies or a source that (i) will sell in single quanity; (ii) carries a good slection of parts, especially Phillips and Motorola power modules [my most immediate need]?

I'm most interested in high power, wideband VHF/UHF modules (30 watts+) for use as a base for a linear amplifier, along the lines of the older Motorola (90?) mobile docking stations, where the HT docks into a unit that allows the HT to be charged, and hooks it up to an audio amplifier, PTT hand mike and the linear.

6BK4. It was commonly used in tube type color TV sets. It's a sharp
cutoff beam triode with a maximum plate voltage of 27 kV and a maximum
power rating of 30 watts. It was used in HV shunt regulator service
at regulator input voltages up to 55 kV. These tubes were notorious
X-ray emitters and should be well shielded in operation. Note: 30 kV
at 20 ma is 600 watts. The 6BK4 is only rated to handle a continous
1.5 ma in a shunt circuit. I don't know how long it would last switching
30 ma.

Message-ID: <3ge1e9$1j4@newsbf02.news.aol.com>
Source record: 114552

I ordered their 1296 transverter with everything. When it arrived I found that it was beyond my ability to assemble the strange stuff with the documentation provided. I returned it and paid them to assemble the converter. I just used it for the first time in last weekends VHF test and it was absolutely great! It only put out 10 mw but using both ssb and fm we made contacts in four grids at distances of up to about 50 miles. I was using a 24 element loop yagi, also from Down East. I am a very experienced kit builder but I wouldn't tangle with their microwave products unless I had particular knowledge of microwave components. You can't even identify the stuff. Now that I have one microwave tranverter that I can easily open and examine I am considering ordering one for another band and putting it together myself.

Good luck - there stuff has all gotten good reviews. See the most recent 73 - I think it review the product you are looking at. Also - I bet the 2 meter stuff has parts that you would easily recognize, unlike the microwave stuff.

Icom will send you a print of their CT-17. Also Icom sells the
CI-V Reference Manual for about $15.00. The IC-735 uses 4 bit data
at 1200 baud, 8, N, 1 You can increase the speed to 9600 baud by
placing some jumpers in the right place. TenTec likes the Icom method on
computer interface they copied it for their radio's too. Also
Optoelectronics uses a variation with their frequency counters and they
sell a CT-17 device.

If you can get an old Icom Ic 502 they are great. Nice small box. Otherwise you might want a new Yaesu FT690RII. I got an FT290RII last summer and it is great. The advantage of the Yaesus is that you can either operate battery or with an attachable amp and all modes. The IC 502 only does SSB and cw and has a rather tight bandspread.

Good luck! 73 - Paul, N6DN

I just want to say that I REALLY appreciate what Gary took the time to explain here...he is a REAL asset to the Group(s).

I would like to extend the question a little further about using an o'scope with a rig. I currently have a TS-850S/AT. Also, have a real nice tektronix o'scope. (quad trace, 300 MHz). My kenwood has a 8.83MHz IF output on the back of the rig to hook up to their "station monitor." Kenwood's station monitor uses the IF for a "pan" display where it displays the signals up and down the band centered about where you are on your radio dial. The Station Monitor gives you the options of picking the bandwidth of the display by selecting scan widths of +/-25 KHZ, +/-100 KHz, and +/- 250 KHz with different scan speeds of slow, fast, and auto, as options.

Q. How can I duplicate or even improve upon what Kenwood is doing and save myself a $1000?

I have a function Generator that can output sin, tri, and sq. waves between 2Hz to 2MHz with adjustable duty cycle. Would that help? I am thinking I just need a ramp (sawtooth?) signal or two. But how to apply them? I don't know a great deal about IF circuits (yet!) so I am somewhat unfamiliar with what would be coming out that external IF to work with it. After I prototype up something with my bench equipment, I would like to build a "box" to do this "pan" display

along with the station monitor Gary described and output this to my scope (when I'm not using it for something else) and duplicate kenwoods' overpriced product (it's functions anyhow). Thanks.

73,

This is an offer for a private newsletter which is an advertisement, right?
An offer to subscribe to advertising is, IMHO, an advertisement in its
own right. The real crux here is the motive behind your postings--it's to
market a product, plain and simple. As far as responding via private e-mail,
well, I hope that my postings will prompt others to complain about what you
are trying to do here. If we let you get started, then we may as well open
the floodgates net-wide. Wouldn't that be a pretty sight--junk e-mail by
the megabyte...

Cross-posted to: rec.radio.amateur.space,rec.radio.amateur.policy,rec.radio.amateur.misc,rec.radio.amateur.homebrew,rec.radio.amateur.equipment,rec.radio.amate

I recently posted a reply to the AMSOFT spam telling them that
instead of asking for a copy of their thinly disguised advertisement
for their CD-ROM, I was sending a copy of their message to their
system administrator.

I sent that message to all the newsgroups AMsoft spammed because most
everywhere their original message went, there are people talking about
burying the instigators under a deluge of email. This will clog the
network and may well cause the people doing it to lose their access.

As I said in the message, the thing to do is to send a message
to their system administrator, which I did, with a copy to AMSOFT.
(The ALL CAPS warning not to send me their ad was to prevent them
from sending me more of their junk mail because of that copy.)

I presume that most people already know this, but a cursory review of the
responses to their luncheon meat attack shows that a lot of people don't.

To repeat (and clarify), the proper response to any kind of spamming
and especially to a _commercial_ spam is to send a copy of the
message to the miscreant's system administrator along with a note
describing the problems they're causing. This is almost always
effective, whereas a reply to the newsgroup just wastes bandwidth and
an email attack will just get the sender in trouble.

>I am thinking about building one but found that
>the part supplier (IDIOM PRESS, PO BOX 1025, Geyserville,
>CA 95441) does not release any ph# for technical/sales
>inquires.

I've used both the original and most recent versions of the keyer software... in fact, I was fortunate enough to have a hand in beta testing version 2 of the software for the keyer.

The Super CMOS Keyer II is very well designed, quite worth the price (for either the kit or the assembled version). It's very easy to learn and use. The designers have included many very useful and versatile features both the for beginner and the confirmed CW operator.

I consider this keyer to be second only to the KC Keyer (which was designed by the same fellows, but which was marketed by another source).

The keyer includes a feature known as ACS (Automatic character spacing). This feature 'helps' the operator to ensure that he/she does not tend to run succeeding characters together into one long jumble. The problem is that new operators, just learning to send, tend to inadvertently not get their fingers from one paddle to the other in time to properly complete a single character. For instance, the character 'Q' (--.-) is often mis-sent by new operators as 'MA' (-- .-) solely because they don't quite get their finger back to the DIT paddle in time to get it started as soon as (actually, just slightly BEFORE) the preceding DAH completes, thus leaving a slight amount of 'dead time' between elements of the same character. This problem is worsened by ACS, because it wants to 'force' a character space (3-bauds) between character elements if it sees more than a 1-baud space between the elements, regardless of whether they're making up a single character or meant as a 'real' character space.

Fortunately, ACS can be disabled while you are learning to send, and then turned back on once you develop a 'feel' for the keying characteristics of the keyer. Do it recommend ACS? ABSOLUTELY(!), but only after you have a chance to get your sending down correctly. ACS is a BIG assistance in sending CW!

The Super CMOS Keyer II kit is about $42, if I recall, and you'll probably spend another $25-$35 on the remaining parts. If you can, use the Radio Shack pushbuttons recommendsd in the original QST article! They're BIG, easy to press, and seem to be very consistent in their ability to make contact 'cleanly'.

I'm currently using a Realistic HTX-100 on 10 meters (until I save enough nickels to get a general-coverage HF rig) and would like to put together a VOX circuit for it. Although it comes with a hand mic, I've scraped together a boom mic using a Realistic 33-1071 cardioid mic (one I bought *years* ago) and some flexible gooseneck. Overall this mic seems to work much better than the hand mic supplied with the rig. Anyway, anyone have any designs for a VOX circuit, or know where a kit or assembled unit might be purchased?

I am interested in learning what is necessary so that I can
design/build/understand electronics, particularly RF circuits.

I ask only a few simple questions, wishing to find some concensus among
those on here :

1) What is the _BEST_ overall book for learning how to build and
UNDERSTAND electronics?

2) What is the _BEST_ overall book for learning how to build and
UNDERSTAND RF circuits?

I am anxious to learn ee stuff, and build my own transmitters, devices,
etc...

PLEASE HELP me out if you can, and point me to the BEST sources for
LEARNING this stuff...

Sincerely,

Michael Fischer

Hello. Steve here in New Jersey. After attending some hamfests this past year, I ran across quite a few pieces of older VHF/UHF gear from the mid to late 70's. Items like Wilson HT's, Clegg mobiles and the old Icom 22 were among some of the tempting pieces of equipment I found. However I didn't acquire any of it. I was wondering if anyone had has any recent dealings with trying to find good quality, inexpensive crystals for older VHF/UHF gear. If so who did you use, what information did you need to give them (I guess requirements differ from rig to rig), what price range did you pay, and what the quality of crystals are. Any information would be greatly appreciated. I'm thinking of resurrecting some gear this spring!!

Yesterday, I bought a portable battery pack (that I expect will have a variety of uses) at what I think is a good price.

Price Costco is selling a Handy Power System, MVP Model I-6001, for 19.99. Outputs provide 3, 6, 9, or 12 volts DC. It must be charged (and recharged) to be used but it does not come with an AC adaptor; although, it does come with an adaptor to use for charging in your car. Nevertheless, I found that a 12 volt adaptor that I already had sitting around the house worked just fine to initially charge the battery pack. LEDs tell you the state of charge.

I took the battery pack apart and found that it contains two 6 volt, 4.0 AHr, sealed lead acid batteries in series.

Now I have one question: Does anyone know where to buy the cheapest, but readily available, solar panels that will recharge this thing?

Better yet, just buy the kits directly from Ramsey and deal with Ramsey directly on any problems. You should have called them directly about it anyway; every time I've had any problem like this (it's been once) with their kits, they have quickly resolved the situation.

While I'll agree that Ramsey's kits vary widely in their desirability, I must say that as a company, I've had nothing but good experiences in dealing with them.

I am building a receiver. In working on the noise blanker I found that some
modern comercial receivers use some sort of controller IC. For example,
the Drake R8 uses an IC marked ULM 3854A. I have looked in IC Master and
not been able to find out any data on this part. Does anyone know who makes
this chip? I would also be interested in any other noise blanker IC
suggestions.

I am also interested in what advantage these parts have over a simple
discrete implementation.

I was reading a series of messages discussing various formats for posting schematics on the Net. I would like to suggest using Circad for the format. By using this program schematics are more than a drawing with symbols. The format allows us to extract netlists as well as B.ill O.f M.aterials and so on. Even better the same program has the ability to create PCB files! Now then, why Circad vrs OrCAD? OrCAD for one is very expensive. Most Hams would be killed by the XYL if they went out and bought it for homebrewing. Circad has a free demo version that everyone can use to read schematics and print them out. The demo also lets you create files (although they have to be fairly small) The commercial version is expensive $995.00 BUT NOT IF YOU ARE A HAM! They get the full version for $299.00 which I think is much more reasonable. Hams who buy it don't get the free phone support but.... I do it myself (for what thats worth <grin>) on my own. I wonder what everyone out in the Net thinks about this? Send E-Mail or Call me during the Day (612) 492-3913. If you want the program call me also! Its part of my very large Site License. BTW its all OK with CIRCADs owner Holophase. 73 de Jay Craswell WB0VNE

Source record: 114424

I'm considering the purchase of the $95 (<---amazing) Ten-Tec
6M transverter kit. I'd like to get some feedback from others who have
built and used it.
I'm also curious as to why they chose 20 meters as the IF frequency
rather than the typical 10 meter IF as used by most other designs !?
I can only think that it has something to do with the IMD
figures...maybe they couldn't be met using this design at 28 Mhz ??
Also wonder what the active devices are and what they are using for
mixers (active or passive) ?
Nevertheless, it sounds like a deal for $95 !

All comments welcome and appreciated.

Thanks...Hugh Duff VA3TO (VE3OYH), Toronto

377. BEST books for LEARNING electronics

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-30 07:57:51 UTC
From: "Mark G.Forbes"
Message-ID: <3gi6cj$mkl@jadzia.PEAK.ORG>
Source record: 114429
Cross-posted to: sci.electronics,rec.radio.amateur.homebrew,ieee.general

>1) What is the _BEST_ overall book for learning how to build and
>UNDERSTAND electronics?

The Art of Electronics, 2nd Ed., Paul Horowitz & Winfield Hill,
Cambridge University Press. ISBN 0-521-37095-7 This is *the*
authoritative reference that I know of. It's *readable*, the sort
of book I leave on the toilet tank. My wife is using it to learn
about electronics. It explains things in sensible ways, without
a lot of heavy-duty math to get in the way. It can take you from
the "What is a resistor?" level to the "How do I build a state
machine using HC logic?" level.

As a side benefit, Winfield Hill lurks here frequently and
posts occasionally too. hill@rowland.org

For your non-technical relatives who'd like to know, sorta, how
the stuff you're doing works.... There Are No Electrons, Kenn Amdahl,
Clearwater Publishing Co. ISBN 0-9627815-9-2 A very light,
humorous book about basic electronics. A plot, too! Really! It
sounds silly (and it is, a bit), but the weird analogies he uses
tend to stick in your mind, and they do make a certain amount
of sense.

Imagine if you will a basketball court, with a long red carpet
stretched across at mid-court. On both sides of the carpet, hordes
of chickens are break-dancing in a frenzy. This is not the *usual*
way of explaining minority-carrier distribution in an NPN
transistor.....but it works! Read the book. It's cheap and a good
laugh.

To order either of these, I'd use Bookstacks Inc. I've used them
before to order both fiction and non-fiction, and they're fast,
easy and Internet-accessible. To browse the stacks and place an
order, telnet to

books.com (IP address 192.148.240.9)

and follow the instructions.

>
>2) What is the _BEST_ overall book for learning how to build and
>UNDERSTAND RF circuits?

You couldn't go far wrong with the ARRL handbook. I don't have the
details, but a local ham will no doubt have a copy, or you can check
books.com for further details. Another place to try is Powell's

Technical bookstore in Portland, Oregon. They also ship anywhere and have on-line ordering capability. Send mail to

ping@technical.powells.portland.or.us

for an automated email reply that will get you started. They are one of the largest bookstores in the world, and certainly the best stocked technical bookstore I've ever seen. And yes, I've been in Stacey's down in Silicon Valley. Powell's is better.

[Posted on 27 Jan 1995 08:07:36 -0800]

I am interested in using a 486-PC to analyze/compute the intensity levels within a room for a 40 kHz ultra sonic transducer source mounted within a medium to large office area containing furniture. For simplicity, the furniture will be modeled using rectangles, etc., and the walls are assumed perfect reflectors.

Are there any programs that will accomplish the above? Can NEC or miniNEC antenna analysis programs be used for this task? What theory applies for ultra sonic analysis? What are the recommended texts covering this topic?

Thanks in advance for the advice and help.

Jim

If my chemistry serves me right, you can neutralize the acid by adding
a buffer (AKA salt water). But with as little chemistry I have, it
just might also cause an explosion, 8-|

FeCl is extremely toxic. The first time I used it, I didn't know where
to get rid of it. I dumped 1/2 cup on the ground, it killed a tree.

Sometime back in the 70's, ham radio magazine had a complete article on replacing all of the tubes in a receiver with transistors. At that time, you could get a minature tube "breadboard" that would plug into a tube socket and it had terminals for mounting components to make up a complete replacement circuit. I doubt that they are still available. I beleive that the article used them.

I have been using the Circad demo version for some time now, and have had occasion to talk to Jay about many features of the program, and I can recommend it highly to anyone looking for such a system. I find the tool extremely powerful, and once you get the hang of it, it is very easy to use. And Jay has been very helpful and informative.

However, I must say to Jay that at $299 (which I agree is a much better deal than $995) is still hard for the XYL to grasp. It even has me thinking (I haven't purchased (yet)). In fact, from what I've seen of Amateur radio in the year and a half that I've been a member, there are a lot of us out here who just don't have the funds that our hobby seems to constantly demand :-)

Still, I would recommend that everyone looking for a schematic/PC-board cad program contact Jay and get the demo version (also available on CompuServe), and spend some time using the demo (it is fully functional except it cannot save drawings larger than a certain size). I have successfully built a new part, entered a schematic, and routed a board for a lead-acid battery charger (from the ARRL handbook). The project definitely taught me what I want in a cad package.

Who knows, maybe Holophase could be convinced to come out with a $99 'Circad-lite' (say for schools/students and Hams?).

I'm very curious where you discovered the information that indicates
it "... contrary to Internet's policy ...". As far as I know, there
IS no such entity as "Internet" to have a policy. Could you be a bit
more specific where you located this policy information? Any sort of
reference will do: ftp, email, http, whatever. I'd like to review
the policy you are talking about before making any further comments.

Thierry-

Often, the slugs are hard to turn because they are ALREADY broken! Sharp edges bite into the inside of the coil form, making it hard to turn.

One possibility, is to use a fine-tipped soldering iron, to melt the material that is used to hold the slug in position. It is often some kind of wax, like bees wax. While things are still hot, it may be possible to turn the slug. Use plastic, NEVER use a metal tool on powdered iron cores.

Thomas-

That sounds like a Sprague part number. However, I couldn't find it in a
1987 catalog. It could be a proprietary part, that can only be obtained
from the equipment manufacturer. If so, the IC manufacturer may not tell
you any more than who bought it from them.

Icom IC4IE 70cms tranciever and HM-55A tone dial speaker-mike
this is Tiny, perfectly formed 70cms/435MHz FM hand held, about this size
of fags.

I am selling the radio (RRP 299ukp), tone dial speaker mike (RRP 74ukp?),
additional 13.8/12v flylead (RRP 5ukp), all manuals and boxed as new.

The unit has extended TX and RX and would be perfect packet station in
your pocket. Sophisticated Power control on RX AND TX as is the ability
to adjust output power from 5w (requires 12v battery pack) down to
20milli-watt.

An ideal first radio for a new licensee.

A mere SNIP at 225ukp ONO. Best offer secures. Buyer Collects from
London, NW6 or pays postage.

You may also want to check some of the literature on mod-anode pulsers used
with UHF-TV klystron amplifiers. Not a perfect fit to your situation, but
there are some similarities.

Check back issues of IEEE Transactions on Broadcasting, or perhaps the
Jerry Whitaker (sp) book on High Power Vacuum Tubes [or a title like that],
NAB Engineering Handbook, etc.

In my humble opinion, I think the AmSoft posting was appropriate.
It told me a new version of the product was available and where
to get more information. It was brief, didn't mention prices, and
was posted ONLY to appropriate (ham radio) groups. This is useful
information.

A few facts:

1. Years ago the Internet backbone was government funded and was only
supposed to be used for non-commercial purposes. That changed about
3 or 4 years ago. It is now commercial with no restrictions on
commercial use. I was the Internet contact for our site at the time
so I got all the official info and saw the significant jump in the
monthly bill.

2. Netiquite (sp?) is not law or a contract between network service
providers and users. It is only generally accepted guidelines
of the culture of the newsgroups. There are many newsgroups dedicated
to particular commercial products used for communication between
manufacturers and customers.

3. There are only a few big companies in the ham radio market. The
transceiver manufacturers, AEA, MFJ, and very few others are big
companies that can afford full page ads. Most of the others are
just one person at-home "basement" operations persued nights and
weekends in addition to regular full time jobs. Don't be fooled
by the fancy names like "XYZ Technologies" or "XYZ Research".
I know several people personally who fit into this category. Most
people feel more comfortable dealing with a big company instead
of a basement operation so it really is necessary to give the

the impression of being bigger.
We should thank and encourage these people for bringing us interesting products that larger companies wouldn't want to be bothered with due to tiny market and low margins.

If some one is truly abusive of the communication channel we should scold him and even ask the site administrator to revoke access. However this was not terrible abuse.

73,
John WB2OSZ

: IS no such entity as "Internet" to have a policy. Could you be a bit
: more specific where you located this policy information? Any sort of
: reference will do: ftp, email, http, whatever. I'd like to review
: the policy you are talking about before making any further comments.

Any of a number of books at your local library or bookstore can fill you in on the history and evolution of what we now call the "Internet". It's original purpose was to connect Universities and other educational institutions for educational purposes. Major advances in this regard were made by the National Science Foundation. Commercial participation was once excluded or severely restricted. The intended purpose of the "creators" was educational advancement (much of it at taxpayers expense), not providing commercial enterprises with new ways to make money. Commercial connections are now common, the limitations on use much more flexible. There are no laws that I know of which prohibit advertising on the net, however the vast majority of commercial enterprises connected to the net honor the traditional "ban" on overt advertising and limit their use to their own research and development purposes and for business communications. They understand and respect the original purpose and intent of what has become the "Internet", and respect the wishes of the majority of users, as well as the wishes of those who have made "Internet" possible.

Virtually every major business from IBM to Intel to General Motors has Internet access. When was the last time you saw a commercial here from one of them?

Again, there are dozens of books that discuss Internet history and purpose. I've not done it, but I imagine you could also come up with lots of similar info if you do a Gopher search on some key relevant topics.

Feel free to let me know what you discover in your research.

Greg

OK, I know it was a typo, but if bits were missing and wrong in the
kit, maybe it really was a *QRT* transmitter.

With kits, the error rate in packing the bits is very high, also
many kits are of designs that are marginal and may need the skills of
someone who could have designed it properly just to get it going....

Heathkits weren't perfect, but they were pretty good and they knew
how important accuracy, checking, and superb instructions are for novice
constructors.

The problem with QEX is it is so expensive for us in Europe. The Same goes for QST unless one uses surface mail, which is very slow. Back issues on CD ROM sounds good. Current issues on the network sounds even better. Is QEX Profit or non-profit? i.e. would there be a problem with Electronic distribution assuming it was sent as postscript with all the adverts included? (I actually want to see the adverts)

Hello brewers,

I am working on a 2 meter SSB transceiver.
MF = 9Mc and fVCO = 135 - 137 Mc (Synthesizered controlled; Works great).

Now i want to mix the 9MC and fvco signal with a diode mixer the SBL-1.

The problem is now that when the MF is transmitting with a Low frequency input of 1Khz(So there
is output) and the vco on 136MC i never see on 145Mc an output signal on the output of the SBL-1. On 9MC its working great.
How works an SBL-1 ; whats the connecting(internal circuit scheme) and how many signals do i need (amplitude). Is het possible to connect the vco signal to the SBL-1 with a capacity!!

HELP !!!

73 PA3GSB the Johan

Thanks in advance!!!! BYE.

Subject: Homebrew VOX

I'm currently using a Realistic HTX-100 on 10 meters (until I save enough nickels to get a general-coverage HF rig) and would like to put together a VOX circuit for it. Although it comes with a hand mic, I've scraped together a boom mic using a Realistic 33-1071 cardioid mic (one I bought *years* ago) and some flexible gooseneck. Overall this mic seems to work much better than the hand mic supplied with the rig. Anyway, anyone have any designs for a VOX circuit, or know where a kit or assembled unit might be purchased?
****
Greg:

Look in an OLD ARRL Handbook (I found a circuit in the 1977 version).
To build an outboard VOX you will need to put the VOX between you mic input to the rig and also put your speaker through the VOX as well. The circuit in the '77 handbook looks pretty good. All of the parts are still quite readily available. The only tricky part is to get the anti-vox control adjusted so that your speaker doesn't turn on the transmitter.

Be sure to shield it VERY WELL. You need to keep RF out of your VOX circuit. I recommend a die-cast box with lots of filtering on the cables in and out of the box. One change you might make from the circuit in the handbook is to use a power FET (IRF 511 is cheap!) instead of the relay for the PTT circuit. This would allow it to be battery operated and have the battery last longer than one evening.

I was REALLY surprised that sometime around 1985 they dropped VOX circuits from the handbook. I guess they figure everyone could figure out how to build one from the description of how they work.

>I can only think that it has something to do with the IMD
>figures...maybe they couldn't be met using this design at 28 Mhz ??

Think where the LO frequency, and it's second harmonic, appear when
using low side injection for 28 MHz->50 MHz (22 MHz and 44 MHz).
That's too close to in-band on both ends (6 MHz) to make filtering
cheap. It's easier with a 14 MHz IF. That displaces the LO fundamental
and second harmonic (36 and 72 MHz) well away from both ends of the
conversion (8 MHz and 22 MHz respectively).

They could have used high side injection to get away from those
problems, but that adds to the cost of the LO string, and does
sideband inversion and backwards tuning. That's Ok in a microproccesor
controlled transceiver where the appropriate sideband switching is
automatically handled and the controls and display made to work any
way you want. It's an awkward pain in a separate transverter/transceiver
combination.

Subject: Noise Blankes ICs. Who makes the ULM 3854A?

I am building a receiver. In working on the noise blanker I found that some
modern comercial receivers use some sort of controller IC. For example, the Drake R8 uses an IC marked ULM 3854A. I have looked in IC Master and not been able to find out any data on this part. Does anyone know who makes
this chip? I would also be interested in any other noise blanker IC suggestions.

I am also interested in what advantage these parts have over a simple discrete implementation.
****

Thomas:

The "ULM" would seem to indicate that it is a part made by Sprague Semiconductor. Sprague sold their semi business to someone else and neither I nor our components engineer can remember who bought them. I don't recall any other manufacturer using numbers like the one you mention. At any rate, it is VERY unlikely that you could find one new. The R8 is a fairly old design. It seems to me it was introduced in the mid 70's. A lot has changed in what constitutes a high performance receiver since then.

For IC implementations you should try to track down old issues of "Ham Radio" and "QST" from the late 70's and early 80's. There were a couple of articles back then on IC implementations.

I remember seeing an article in a ham magazine (I think) quite some time ago that was sort of theoretical. It may have even been written by Dr. Rohde. I seem to recall that whoever it was did some research and found that the impulse energy that did the most harm had a significant amount of energy in the 40 MHz range. He used an auxilliary antenna just for the noise blanker and a small "receiver" whose job was just to detect the noise pulses. This then generated REALLY sharp pulses which were applied to an analog switch of some sort in the IF of the receiver. It was a very good article. I wish I had a copy of it.

Maybe Zack or someone else at ARRL remembers the article I am thinking of.

Ben:

500 Hz is very slow in the switching world. Have you considered
switching the low voltage side? You probably don't have that much capacitance
on the high voltage side, so it would decay pretty rapidly.

If you are using the AC mains (60 Hz or 50 Hz) that might be a problem.
If you changed your power supply to a switching circuit at 10 KHz or higher it
would definately be easier to just turn the low voltage side on and off.

Ok, Vince, you can build your own panadaptor and save some money, but
it's not a trivial project. What a panadaptor is, is a limited spectrum
analyser. It samples the spectrum around the IF frequency of the receiver
before the narrow filters, feeds that to a mixer driven by a swept LO,
filters and amplifies the output of the mixer, and envelope detects the
signals. The detected envelope is then run through a log amp which feeds
the vertical plates of the scope. The horizontal sweep of the scope is
driven by the tuning ramp voltage for the panadaptor's LO.

So, you need a mixer, a SBL-1 will do, and you need a ramp to drive
the LO tuning, your function generator will do. You'll need a LO
that can be voltage swept from 7.775 to 7.975 to see the signals
+/- 100 kHz from the receiver's frequency. That's not too hard,

though it can be tricky to get good repeatability, tuning linearity, and stability from such an oscillator. It might be better to sweep a higher frequency VXO and hetrodyne it down to the 7.775 MHz range. Or alternately, you can *predistort* the ramp voltage so that you get a linear frequency change per unit time. You may need to do both to get an accurate linear frequency display.

You'll need an IF amp and filters (455 kHz) you can switch for different resolutions. At minimum you'll want 3, a CW filter for high resolution, a SSB filter for medium resolution, and an AM filter for coarse resolution. Different resolutions will be wanted at different spans, and for different sweep rates. The higher the frequency resolution you want, the narrower the filter you need. With narrow filters, you have to slow the sweep. For wide spans, you can't slow the sweep too much or you'll get horrible flicker on a non-persistant display tube. So you need all the combinations, coarse resolution with a fast sweep for wide spans, and finer resolutions with slower sweeps for narrower spans.

Now you need an envelope detector, this is trivial, just a precision rectifier. And you'll need a logarithmic response amplifier to boost the envelope for display. This is not trivial if you want accuracy. A good log response amplifier will take a bit of doing. Of course you can just use the linear response vertical amplifier in the scope, but it's dynamic display range will be so limited as to be useless most of the time. About all you could usefully use it for is signals that vary by no more than about 10 db across the span. Since you'll typically be seeing signals with level variations of at least 60 db, you need a log response amplifier. If you want to view signals from the receiver MDS up to its blocking limit, you're going to need better than 120 db log response.

So you see, a panadaptor has most of the circuits of a full receiver, plus a few. Its one saving is in not having to have a true front end, that's supplied by the Kenwood. Fortunately, there are single chip receiver subsystems that can come to your rescue if you can tolerate some performance loss. The MC13135 is one such chip. While nominally a FM receiver chip, it has a log response RSSI output with a 65 db range that can be directly applied to the scope's vertical input. You can use a selection of 455 kHz filters with it, and you can VCO it's first LO, feeding that back into the second mixer which will be used as the input for the device. It's a bit crude and rude, but it'll work. With what you've got already, parts cost, not including filters, should be under $20. Still, a panadaptor isn't what I'd call a novice project. To become a useful instrument, it'll need considerable understanding and skill to build it.

Gary

A dodge I remember reading somewhere is to heat the core up carefully
with a soldering iron. This softens the wax, or whatever it is. Probably
worth trying before using solvents.

The Philips TDA7000 is what you are probably looking for. They work
quite well, and some people have used them successfully for packet reception
on the 2 m band.

409. Linear Power MosFet FAILURES...my experience

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-01-31 22:00:57 UTC
From: gene@eagle.csl.uiuc.edu
Message-ID: <gene.791589657@eagle.csl.uiuc.edu>
Source record: 114458

>> Ian Clark Power MOSFET failure Modes?

I'm glad to see more people are beginning to explore the possibilities of low-cost Power MosFets for High-Power linear amplifiers. It's an interesting frontier and, like investing in the stock-market, you need to accept the risk-factor that inevitably goes with it. I posted some of my experiences about a year ago...full-wave rectifying the 240 AC line, for a D.C. output of 165 volts at 10 or 15 amps capability. Actually, at reduced power, I found that half-wave rectifying 120 AC was satisfactory with my 18,000 ufd of filter (two 36,000 ufd @ 75 vdc in series..with shunt 1K-10W equalizing resistors across them). 'A little over-voltage, but with no apparent problem. I ran AC-neutral to an isolated common inside the case, so that the case and RF-in and Ant-out (which were both isolated from internal circuity) could be at case & earth ground. Large computer-grade capacitors of that type show up frequently at Hamfests.. I paid $2 each for mine. About a year ago I had used 8 IRF-722 (400v) in push-pull parallel. I used a tuned broadly-resonant push-pull tank-circuit in the output (about 60 ohms drain-to-drain impedance at 900W out). It worked well on 160M but required post-filtering on 80M.
Recently, I rebuilt the amplifier using sixteen IRF-710 MosFets....again in push-pull parallel. These were only rated at 20W instead of 40W, but had less than 1/3 the input capacitance per unit. Mounting sixteen is not as awsome as it sounds...drains are not insulated from the heat-sink, and half of them can be mounted on the underside of the same heat-sink, using a commom bolt and nut. (be sure to scrape some of the non-conducting anodized surface off of one side to insure electrical contact). Stray capacity of the isolated mounting of two separate heat-sinks will be insignificant because the tuning capacitance on 80M will be 0.016 ufd (six 0.0027 ufd 500v micas in parallel for the high-current required, from each heat-sink to common.....and twice that much on 160M for an Xc of about 5 ohms and a loaded Q of about 10).
Since I have posted some circuit details in previous months, I will summarize here by saying that it was performing beautifully on 80M using a resonant tank circuit inductor of "one-turn" of 1/4" tubing about 4 1/2" diameter (which resonates with the afore-mentioned pair of 0.016 ufd in series) and very clean carrier sine-wave, or very faithful two-tone test pattern....with no post-filtering required. As previously mentioned, the output to the 50-ohm antenna is simply an insulated wire inside the 1/4" tubing going to the case-grounded (also earth-grounded) 50-ohm antenna coax. The input is isolated via a broad-band toroid 1:1 transformer, and requires only 15 or 20 watts...most of which is dissipated in lossy series 25 ohm, and shunt 12 ohm to each half of the push pull input. All gate biases are common to the same bus, although each of the sixteen MosFet source-pin is individually biased with a 3.3-1W carbon-comp resistor (un-bypassed).
.......And now for the bad news....I was so pleased with the beautiful performance that I was about to start writing it up for submission to

"Worldradio" magazine (since they have been receptive other articles I have submitted)....when POW...I apparently left the two-tone pattern on a little too long and one group (eight IRF-710's) all shorted. Surprisingly, when I disconnected this group and operated the remaining eight in single-ended fashion, the nice undistorted pattern still remained, though of course at only half the previous power. I had previously tested it for a few hours using a little two-tone test generator that I had built which plugs into the ICOM transceiver microphone input (and gets +8v power from there). It was gated for about 1 second ON followed by 3 seconds OFF which the amplifier seemed to tolerate OK for several hours (good heat-sinks and muffin-fan airflow).
Incidentally, this is a good device to run your transmitter while you run next door to check and/or help solve Radio-Interference (returning every 10 minutes to station-identify).
Another feature that I would recommend....use slow turn-on Power MosFet such as an IRF-640 to gradually short out a 100 ohm In-rush current limiter between the rectifiers and the 18,000 ufd capacitor. I happily found that when the BIG Short occurred, it opened very fast (blew out), but performed as a very fast-blow fuse. This protects the rectifiers, the power-on toggle switch, the line fuses (or house fuse), and the 3.3-1W source resistors....i.e the remaining 100 surge resistor limits current to 1.5 amps. Of course, the +9v bias supply to provide the RC-timed turn-on voltage for the gate, must be isolated since it rides on the +165 vdc supply. I used a 9v Duracell which has a shelf life of 5 yrs. I use a SPDT relay to discharge gate on power-down while disconnecting the battery.....virtually no drain on the battery at any time.
ANYWAY, MY PRESENT TENTATIVE THINKING CONCERNING FAILURES of MosFets...
based only on my experience, is that we can be very naive concerning the ratings listed in the Data sheets. I believe they probably are mostly concerned with DC (remember, these are not touted as RF MosFets...they are only low-cost ($1.47 each for IRF-710's from Newark Catalog). I believe that when operating at 4 MHz we seriously underestimate how quickly internal dielectric heating can become intense in such a small plastic package...even though it's well heat-sunk. I plan to scale back my expectations to 600W PEP on 80M, and 900W PEP on 160M..(ssb voice except for very quick tune-up spurts. Note that 900W is about the limit with this 165 vdc supply because each drain max swing will be between about +10 to +310 (due to fly-wheel of the resonant tank). This provided 600v p-p across the 50 ohm antenna which is about 900W out. Note that this is only about 1.3db down from the legal max of 1500W.
I now have very nice efficient heat-sinks with one muffin-fan pulling air out of the cabinet. I believe I will add an additional one to push the air in the intake opening. The MosFets requires remarkably low quiescent current...about 1/2 amp for the total sixteen, and this should keep the MosFets cooled well enough to tolerate reasonable bursts of output power.
A final note...when I went to order more IRF-710's from Newark, they were out with no prospect for several months, so I ordered second-best IRF-712's (same price and specs except slightly lower I-max..and slightly higher Rds on but that probably won't much effect using it as a linear ampl.

I agree that people shouldn't throw the "policy" terminology around,
especially because the attarction of the NET is that there are really no
hard and fast rules....things happen or do not happen as a result of
"gentlemens' agreements"

Use of the NET for commercial purposes is tempting, but my opinion is
that the best thing to do is for "advertisers" to voluntarily restriuct
their postings to areas set up for it. Otherwise, can you imagine what
some "enterprising" commercial entities would do to these USENET groups?

I use the word "enterprising" in quotes...these people are the same ones
who believe that they are "clever" when they park in a handicapped
parking space and get away with it, and that the rest of us "saps" were
not thinking or not willing to take a risk. We could legislate against
boorish behavior on the NET, but lets hope it never goes that far.

And in case you are wondering, Hank, I'm not some fresh-faced college
kid cooped up in my dorm room pecking away at my computer
at 2:30am philosophizing about how the world SHOULD be (not that there
is anything wrong with that). I'm a professional marketer with a real
soft spot for advertisng and business.

According to the MO Dept of Natural Resources, Hazard Waste section,
FeCl can be disposed of down a drain... WITH A LOT OF WATER... I'm sure
tha, if not diluted, it would do damage to plant life if poured out
directly.

Thanks for your added comments.

Congratulations....This is the first LOGICAL and UNEMOTIONAL
response, I've seen to this issue. Actually, if more people
would have taken your attitude, and not started exploding
flame mail (do I get flamed for saying this?) it would have been
over quickly. As it is, AMSOFT has gotten TONS of free
advertising, and more word-of-mouth exposure than they ever
expected.

I kind of liked the touch on the part of one AMSOFT rep
who just recently put the WHOLE AD on each of his replies
as his signature file -- nice touch!

As a HAM who let his ticket expire 20 years ago (when I
got married and then joined the USMC), and is just this next
Tuesday re-taking the exam, I have just one question...

Do you guys behave this way on the air? My experience
has always been that of the courteous HAM. Helping the
Novice and "gently" correcting anothers mistake or
indescretion used to be the rule.

I, for one, would try expressing my opinion directly to
the miscreant, rather than e-mails to admins (which
obviously did nothing). I think the folks at AMSOFT might
have responded more favorably to a reasonably-voiced
complaint than to naked aggression. Also, be aware that

AMSOFT needs the HAMS to purchase their goods, so
I don't believe they'ed intentionally want to annoy us to
point of not buying their product(s).

Try reading Wayne Ryder's (W6URH) article in the latest Communications
Quarterly on his homebrew HF transmitter. It has a reference to
a previous article he wrote on a homebrew HF receiver. Wayne, like you,
was a Navy technician. Hence if he can build it, you should be able
to.

Why does world.std.com sound so familiar? Wasn't someone at that
site also posting ads on the rec.radio groups? This might explain
your `humble opinion':

>In my humble opinion, I think the AmSoft posting was appropriate.
>It told me a new version of the product was available and where
>to get more information. It was brief, didn't mention prices, and
>was posted ONLY to appropriate (ham radio) groups. This is useful
>information.

It was posted to *all* the radio groups many times. If only one post
to .swap had been made no one probably would have minded.

>A few facts:
>
>1. Years ago the Internet backbone was government funded and was only
> supposed to be used for non-commercial purposes. That changed about
> 3 or 4 years ago. It is now commercial with no restrictions on
> commercial use. I was the Internet contact for our site at the time
> so I got all the official info and saw the significant jump in the
> monthly bill.

A very large portion of is is still government funded: State taxpayers
foot the bill for the .edu sites (millions of dollars per year here
to run 5 unix mainframes for 45,000 students/faculty and to pay the
long DX telephone bills to all points in the Pacific). Keep in mind
that a good portion of the traffic that has originated at non-.edu
sites gets passed through those sites. If the state government-funded
.edu sites each pulled their plug Internet would probably cease to exist.
Thus, your `fact' isn't quite factual.

This is the more current thinking, probably closest to fact.

>
>
>Any of a number of books at your local library or bookstore can fill
>you in on the history and evolution of what we now call the
>"Internet". It's original purpose was to connect Universities and
>other educational institutions for educational purposes.

I must disagree herre, don't always believe what you read!! Just because it
is in print does NOT mean that it is in the least bit accurate. In the early
70's the "Internet" as you call it was born out of DARPA, Usenet, and several
other "local" networks. It's original purpose, no matter what is claimed
after the fact, was NOT to connect Universities. It's main purpose was to
allow exchange of information between large gov't agencies and their sub-
contractors, typically universities and such. Don't confuse the facts.

>Major
>advances in this regard were made by the National Science Foundation.
>Commercial participation was once excluded or severely restricted.

I agree with the first inthat the NSF funded research and development along
with others. However commercial participation has always been an important
part of the net...just ask BBN, DEC, etc about this. Ithink the difference
here is that it was better self-controlled... (opinion mine)

>The intended purpose of the "creators" was educational advancement
>(much of it at taxpayers expense), not providing commercial
>enterprises with new ways to make money.

BZZZZTTT! Wrong again read above...it was a gov't funded program...

>Commercial connections are
>now common, the limitations on use much more flexible. There are no
>laws that I know of which prohibit advertising on the net, however the

>vast majority of commercial enterprises connected to the net honor the
>traditional "ban" on overt advertising and limit their use to their
>own research and development purposes and for business communications.

See the above on peer pressure, self control, etc..

>They understand and respect the original purpose and intent of what
>has become the "Internet", and respect the wishes of the majority of
>users, as well as the wishes of those who have made "Internet"
>possible.

Again youmiss the point, read some of teh comp.sys groups and see how well
the big vendors "respect the wishes of the majority". Those companies use
the net as their own....whether you agree or not, that is the fact...

Internet is/was made possible by large donations of money, time and hardware
from big business and the government. Not by some collective of users or
universities. If we waited for academia to decide how to do things we would
still be waiting for an 8bit computer... Keep this inmind as things move
on and we "bite the hand that feeds us" turning the net over to the MCI's,
sprint's etc of the world.

>
>Virtually every major business from IBM to Intel to General Motors has

>from one of them?

Read the correct groups and you will see in some way shape or form either
blatant or subtle adverts from them all. They are not going to miss out
on a chance to target their market. How better to beat demographics?? If it
isn't happening in "your" group, IT WILL!

>
>Again, there are dozens of books that discuss Internet history and

The ARRL Handbook has a good receiver - the High Performance Communications Receiver - in it. Check Solid State Design for the Radio Amateur by Wes Hayward. The Radio Handbook edited by Bill Orr used to have some very impressive HF multimode transciever projects in it, but I haven't looked through it for a few years. The series about single-signal direct conversion receivers and transmitters that ran in QST two years ago might have possibilities; definitely a multi-mode setup. Let us know what you fine, David.

A lot of good chemical discussion recently on Ferric Chloride for board etching.

I have some Ammonium Persulphate (?) we used in school, that is in crystaline form. We had to mix with water and heat it to get it to react with the board, but it was certainly a lot cleaner, thinner, and non-staining, compared to Ferric Chloride. Why isn't this stuff sold at Radio Shack, et al? It seems much more convenient to use (and sell) in its powder state. Are there environmental concerns with it? Is it more expensive?

: It does work - I've seen it in OE5JFL's shack and others have
: reproduced it. As an alternative to opto-triggering three or four
: 1200V thyristors in series, is there a source of relatively
: inexpensive thyristors rated to 3-4kV? The device only needs to be
: rated to handle about 10A continuous, because there's a series
: inductor to limit dI/dt and take the 'sting' out of the current
: transient.

: In days of old it would no doubt have been done by a large glass
: something-tron, but I'd prefer a compact solid-state solution.

: Any ideas, please?

Ian! 3kV 10A continuous! shame on you! what about the 400W
PEP UK limit?

You could well have a visit from nameless government agents asking
searching questions about trigger devices for nuclear weapons :-)
(How many radcom columns have you in the pipeline - so I'll know when
to check if you've disappeared- ?)

More seriously, The OE5JFL approach sounds right. You need about 4
serious thyristors in series. I'd not use opto isolators. Transformer
coupling to the gate-cathode inputs is far easier. You won't need many
turns,and can wind something with thickly insulated wire. Sensing a fast
transient can also be done with a transformer. Your thyristors will need
voltage sharing resistors.

You have 135 joules to dispose of. A bit much for thyristors to
absorb. Series L will not help, it will throttle back the dI/dt, but
will cause a ring with stray C that may well turn your thyristors off.
Methinks you need to have something to dump the energy into for more
leisurely dissipation.

You could use a single gate drive transformer provided you use gate
resistors to share the drive current.

How about a monster size Xenon flash-tube? make photographers
jealous!

Cheers
David

Boy this brings back memories. I built (and still have) a Ignitron dump system that would turn off a 6 kV supply by firing dump tube and turning off Triacs on primary of supply. Unfortunately it is hybrid with mostly solid state but a dump tube and dump tube driver. It delivers around 6 kV at two amperes, and you can short it with a screwdriver while it's on and it just "tics" and turns off! Have fun during testing, (if it fails to operate) be sure you are wearing goggles and have a fresh pair of under garments.

425. GAMMA or T Match on YAGI: HELP!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-01 16:56:24 UTC
From: white@julian.uwo.ca
Message-ID: <white.14.00855D09@julian.uwo.ca>
Source record: 114377

I'm trying to build a 3 or 4 element YAGI but I'm having trouble with matching the impedance of the antenna to the line. I don't care how I do it, but the simples ways seem to be using a Gamma or T-Match.

I only do listening, which means I don't have a transmiter to check the SWR of the antenna. (at least I don't think I can with my current equipment) This is the root of all my problems because the ARRL and most other books assumes you can find standing waves on the antenna.

I have read sections of the |ARRL. Section 16-7 talks about T and Gamma matching but there method requires finding SWR. Section 17-17 in figure 37 shows both a Gamma and T match but does not give the spacing between the connectors for either. (how could it as it varies depending on the resonance of the antenna?) Basically what I'm looking for is a good guess as to the distance between the conections, and some more information about the matching systems.

I don't understand the purpose of the Gamma rod or the T rods shown in figure 37, 17-17 of the ARRL. (wait: are they an easy way to keep the distance x (the space between the antena and the line) constant? If so should the rod come to the centre of the antenna? Does the total length of the rod matter? ie. The book refers to the rods as being adjustable, does this mean the length of the rod is adjustable, or the position on the antenna is adjustable?)

Here is what I think I need to know to match the impedance:

- the spacing for the connections

- what lenght the gamma rod, or T rods should be. (maybe answering the previous question answers this one?)

- what range the variabe capacitors should be

Here is some information I think might be relavent to my problem.

I building a 3 or 4 element YAGI (will probably build the 3 element and if it's OK then a 4 element)

75 ohm reciever using coaxial cable as a feeder

I'm using standard copper plumbing tube to as the elements, They will be mounted on wood. The elements will be spaced .20 wavelengths apart.

I will likely produce my first antenna for the one meter band, and later build something larger. If its possible to give estimates in terms of frequencies I would be thankful.

Right now I have no idea what the spacing should be, so if you could give me a clue that would be great (I realize it's propably imposible to get it exact, but I need a starting point. Then I can play to see whats best)

If this is on the FAQ sorry, please direct me to it

If there is a good book with all this stuff in it (for beginners) tell me.

Thanks for your time

Steve

I vaguely remember a co. called Ray Jefferson (?), with a Ray-Jeff brand (?)
in the marine electronics business, at least 10-20 yrs ago. Don't know if
they're still around. Perhaps calling 800 assistance using this name would
help. Or ask around at a marina!

The SBL1 requires 5mW into 50 Ohms, which makes it 1.4V peak-to-peak.
A catch is, that it requires 50 Ohms termination also for the unwanted
mixing products, i.e. so called diplexers.

I found the Minicircuit people very helpful as to data sheets,

I think it won't.

Most "major businesses" like IBM and General Motors have a Public
Relations department for such "market targeting." There are usually
specific personnel policies to discourage individual employees from
engaging in "public advertisement" of the company. Ever see a .sig
with a disclaimer about not speaking for one's employer? :-)

"Corporate entities" are usually pretty paranoid about offending
people, and advertising in newsgroups tends to offend many people.

If the material is wax it can be melted either with a iron or a hair
dryer, but if it is a pait type, try finger nail polish remover. Use
a cotton swab only on the sealant, giving it several coats as the polish
dries. The point is to keep the sealant moist with remover until it
can be scraped off or loosened up so that you can turn it. Finger nail
polish remover should be mild enough for most coil forms but use it
sparingly in case it does decide to attack the form.

35th Lafayette Hamfest
March 10-11-12, 1995
Holidome - Holiday Inn Central
Lafayette, Louisiana

The 35th Annual Acadiana Amateur Radio Association (AARA) Lafayette Hamfest
will be held at the Holidome just south of the intersection of I-10 & I-49.

There will be commercial dealers, a flea market, technical forums, tours for
those interested in the area's attractions, the famous AARA fox hunt, and
plenty of Cajun hospitality.

The Quarter Century Wireless Association (QCWA) Cajun Chapter #189 will host
a dutch treat breakfast buffet at 8:00 a.m. on Sunday, March 12th.

FOR MORE INFORMATION:

If you'd like to find out how you can reserve swap tables, or pre-register,
or attend the V.E. test session, or anything else..... Please contact:

Brian -- funny meeting you here while surfing! Please add the following to your list:

MXM Industries
Route 1, Box 156c
Smithville, TX 78957
(512) 237-3906

Owned and operated by Bruce Williams, WA6IVC.

Offers line of QRP kits including single conversion receiver, about $50.00, 3 watt tranxmitter, about $30.00, Receiver/transmitter (the two above on a single board), about $80.00, and a dynamite transceiver, double conversion receiver with crystal filter, 3 watt transmitter, About $130.00. A SASE wile bring a catalog. ALl kits are complete except for cabinet and misc plugs and jacks for antenna, power, phones, and key. All kits come with a "if you can't get it working we will". Getting it working charges run about $15.00, exclusive of customer damages.

I don't work for Bruce, but I once did -- he was my boss in the aerospace industry from 1974 through 1985. He puts a real quality product out there for a reasonable price. His rigs are so much superior to most of the junk that's being sold out there it's a shame he doesn't get more publicity or do more advertising.

Thanks,

W6TOY/3

>2) What is the _BEST_ overall book for learning how to build and
>UNDERSTAND RF circuits?

I think a good place to start is with the ARRL Handbook for Radio Amateurs.
It is packed with many designs, and explains the theory of RF quite well.
Can be ordered from most Ham outlets.

>I am anxious to learn ee stuff, and build my own transmitters, devices,
>etc...

For pure EE information I use the Bushbaum's Complete Handbook of Practical
Electronics Reference Data by Prentice Hall. Can be ordered from most
bookstores.

In my understanding, FeCl3 is not strictly an acid (no H+ ions), but
rather a salt which contains lots of Cl- ions, which latch onto the
copper and form copper chloride. That's why the solution turns green.

The safest way to get rid of your FeCl3 is to use it up etching copper!
The resulting compounds are not nearly so reactive. It may not be the
fastest way to etch boards, but it's the most "ecologically responsible".
When the solution is used up, dump it down the toilet and flush several
times. (and hope you don't have copper drain pipes ;)

Nah, 10A is the thyristor rating. The 3kV supply is only 1A continuous...
Actually it's for the EME system and I do have a QRO permit for that,
not to mention a lot of unavoidable cable loss.

> More seriously, The OE5JFL approach sounds right. You need about 4

> leisurely dissipation.
>
>
Sorry, I missed something out of the previous description of the
OE5JFL circuit. It is triggered by the voltage drop across a 10R
resistor between ground and the negative terminal of the smoothing
capacitor. That's where most of the energy goes.

```
diodes ---+---L-----+-------B+ output
| | |
```

```
Tfmr C Th
| | |
diodes---<X>--R-----Gnd
```

The inductor is 100-500uH, (10m of enameled copper wire) giving a resonant frequency of about 2kHz and a Q of less than 0.25 when the thyristors fire.

Provided the 10R resistor can handle the peak current, 135J only represents the equivalent of 1A for 13.5 seconds, so anything over 10W rating seems OK.

Current is sensed by the ground-referenced negative voltage at point <X>. This triggers a flip-flop, which turns off the solid-state relay in the AC line to the primary and also fires the string of thyristors via the opto-couplers. The transformer-triggered circuit would probably work, but the trigger points might be dependent on the characteristics of the individual devices... and I would like to be sure that the circuit will work first time.

As Tom, W8JI put it: If it doesn't work, be sure to wear goggles when you short the B+, and have a change of underwear handy.

446. Help restore PBT to IC-275/575 etc.?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-02 19:15:38 UTC
From: w0uc@aol.com
Message-ID: <3grb0q$6j2@newsbf02.news.aol.com>
Source record: 114495

I am looking for someone who has restored the Pass Band Tuning function to an IC-x75 series transceiver (on later models, the control is used for "data level"). It appears everything is still in place, the control just needs to be rewired. Access from the front panel looks very difficult; re-wiring the Main Board end is another option. Anyone with any experience out there?

In article <D3Bopu.Dvt@ruacad.ac.runet.edu>, ddabay@ruacad.ac.runet.edu (Dave Dabay) says:
>
>I must disagree herre, don't always believe what you read!! Just
>because it is in print does NOT mean that it is in the least bit
>accurate. In the early 70's the "Internet" as you call it was born
>out of DARPA, Usenet, and several other "local" networks. It's original
>purpose, no matter what is claimed after the fact, was NOT to connect
>Universities. It's main purpose was to allow exchange of information
>between large gov't agencies and their sub-contractors, typically
>universities and such. Don't confuse the facts.

One amplification of something alluded to above: these messages are
part of USENET, which is NOT the INTERNET. It's always been my
understanding that different policies apply to the small part of the
internet that is usenet. I have no problem with IBM or any other
commercial organization sending email or files via the internet or
setting up FTP sites or Webservers or engaging in any other kind of
commercial activity on the internet. Having my tax money pay for
those activities is like having trucks on the Interstate - I can live
with it as long as they stay out of my way.

I _DO_ object to commercial messages on USENET. I don't enjoy having
my tax money used to pay for somebody to send me advertisements that
are mixed in with the legitimate messages in such a way that it's
extremely difficult to avoid them. That puts me in the position of
paying to be annoyed. If it gets bad enough, I'll say to heck with
it and stop reading the messages. Needless to say, if my congressman
then announces that dropping government subsidies to the usenet would
help balance the budget, I won't object very strongly.

After all, why pay good money so somebody can annoy you for their profit?

Perhaps we need rec.radio.commercials?

449. Make TNC?

From: copeland@fohnix.metronet.com
Message-ID: <3grltp$sub@fohnix.metronet.com>
Source record: 114498

Is it possible to make a TNC with a regular modem and some software?

Packet sounds like regular FSK modem, but are they the same?

Seems a regular modem with "packet software" running would work.

```

What I discovered is that there is no longer any restriction on
the use of the net for commercial purposes.

I've been "on the net" since well before ARPA funded the initial
connectivity between commercial (not educational) users. Some of
those users WORKED at universities, but the projects which used
the ARPA backbone and the various ad hoc interconnections that
existed prior to the backbone didn't do it just for fun.

Perhaps you need to look at those books (and papers and other documents)
before you make assertions about history.

it would depend if the published data was in electronic format.

i guess something like Adobe's Portable Document Format would do (since there's readers for dos/windows/mac/unix (os/2 supported through windows 8( ) would do for making the data "universal" and still keep it searchable and maintain good resolution (you zoom in on bitmaps and you get blocks - you zoom in on a .pdf and you get larger letters and such since they aren't just bitmaps..)

can't search a bitmap...

and the PDF readers are free...

if things go well, i might get a chance to have some time on the distilling tools used to make pdf files so i'll have some first hand knowledge of the limits in the creation of new documents.

no doubt microsoft has something else, but of course, no support in the areas microsoft doesn't sell to...

Thanks Norman.

I already have a 950-1450 tuner which I use in my spectrum analyzer. I want to expand the frequency range and use it for a downconverter on 1691 and other frequencies in that frequency area.
I think I would have to get the tuner from Europe where they use the 950-2050 MHz range. Today, they are also using a 700-2050 MHz tuner, a nice wide band spectrum analyzer! I would like one :)

Sounds interesting. I remeber that the tuners we have go to 1750Mhz.
It is getting real difficult to find tuners only most have demods built in.

I think microphonics could be an issue. The phase noise is low enough for use
with narrowband FM.

We used a tuner with a 70 mhz IF 6Mhz saw filter. Mixed it to 10.7 and
then to 455Kkz as a beacon receiver. A common referance was used for all
synthesizsers. Three synthesizers were used. This allowed for 1 Khz tuning
with low microphonics across the entire band.

Some time ago I posted a message about the Amiga Amateur Radio User Group.

Unfortunately shortly afterwards and for reasons outside my control my
E-mail address got cut off! I know several Amiga using amateurs tried to
reply but got bounced E-Mail.

In brief the AARUG is UK based but welcomes members from anywhere in the
world. There are already several hundred members. The AARUG publishes an
occasional newsletter and maintains a radio PD library. Membership is free;
the group runs entirely on voluntary donations.

There's an introductory floppy disk available containing details of how to
join, member lists, old newsletters and the PD list. For more information I
can now be contacted at my Internet address: paul.whatton@posnet.co.uk or
via FidoNet at 2:254/214

Johan Maas, PA3GSB (jmaas@aston.baan.nl) wrote:

> How works an SBL-1 ; whats the connecting(internal circuit scheme)

The SBL-1 is a double balanced diode ring mixer. It is a bit hard to draw the internal schematic in ASCII, so I will try to explain it.

Put a diode ring (4 diodes with the arrows on the diodes pointing in the clockwise direction) in the middle of the schematic. Put two transformers with center tapped secondaries, one to the left and one to the right of the diode ring. The secondaries are connected to each own corner of the diode ring.

The center tap of the left transformer is grounded (and it is available on pins 5 and 6 on the SBL1). The center tap of the right transformer is labelled IF-port (and is available on pins 3 and 4 and please note, pins 3 and 4 must be connected together). As there is a direct connection to the diode ring, the frequency response of the IF port extends from DC to 500 MHz, so this is the only port that can handle audio frequencies in modulator/demodulator applications.

The primaries of the left and right transformers are the LO and RF ports with a 1 MHz to 500 MHz frequency range. The manufacturer (Mini-Circuit) has chosen to call the left port (pins 7 and 8) the LO-port with pin 8 'hot' and pin 7 LO-ground. The right port (pins 1 and 2) is called the RF-port and pin 1 is the 'hot' pin and 2 the RF-ground pin.

> and how many signals do i need (amplitude).

The LO power should be about 5 mW (+7dBm) while the signal power should be well below 1 mW (0 dBm) for low intermodulation.
The MAR-3 MMIC amplifier should be able to generate a sufficient LO drive to the mixer.

> Is het possible to connect the vco signal to the SBL-1 with a capacity!!

The RF and LO ports are allready AC-coupled to the rest of the circuit (through transformers), so I don't see why not.

NEC/Mininec programs model collections of wire segments (plus the
effect of ground). They aren't anywhere near what you need--sort of
like measuring the circumference of the earth with a 6 inch ruler.
It takes a huge amount of wire segments to model a plane reflector.
Not that it either couldn't be done if you threw enough money at it.

Perhaps you might look at optical models. Undoubtedly the Navy
has lots of information on using sound to image objects, but I
have no idea if you could get at it.

YES!!! Someone else who had/has worked onthe "net" since before it
existed, "according to some sources" (dave says tongue in cheek)

Again, as they say in the newspapers (Martie Zad, Washington Post, circa
1978): Don't believe ...anything you hear,
half of what you read,
or some of what you see.

Keith et.al.,

Try Tanner Electronics at Beltline and I-35 in Carrollton.
Tanner's is on the SE corner of the intersection, i.e. on
the west side of I35.

He has a good supply of odds and ends for experimenters, etc.

This is NOT an advertisement. :-) Just another satisfied customer.

I've used solar panels since 1973 when they were REALLY expensive.
There are several reputable manufacturers out there to choose from.

The suggestion about kite antennas is a good one. They work really well
on a mountaintop because you can be certain of enough breeze
to keep them up. Stretch a counterpoise along the ground and
you will do quite well.

Do you have evidence to back up this assertion?

It is *illegal* to park in handicapped parking spaces, at least
in most jurisdictions. It is not *illegal* to post commercial
messages to usenet. You have here compared an *illegal* act to
an act *which you personally consider objectionable*.

If you wish a newsgroup without advertising, then you should take
those actions which will lead to such a newsgroup: a call for
moderation of the group, or a call for a new (moderated) group.
Within usenet, this is the only mechanism available to control
content - other than peer pressure ... and you will lose this one.

: When the solution is used up, dump it down the toilet and flush several
: times. (and hope you don't have copper drain pipes ;)

Dear Pierre,

I question this practice. Here in the San Francisco Bay Area it is illegal
to use Copper-based products for killing tree roots in sewer pipes.
This is because Cu is a deadly toxin to aquatic life. The treatment
plants just can't get all the Cu out when it is diluted in millions of
gallons of water, and it wreaks havok when discharged into the Bay.

I'm sure a similiar story can be told for most other communities.

Please dispose of etchant at your local municipal dump. They should
have a specific tank for this stuff.

Since you have an ample supply of stepper motors, you may be
able to make the remote tuner stepper motor move by wiring it in
parallel with an identical one in the shack sort of as a master/
slave servo configuration. No external power will be needed.
Calibration won't be possible though.

From: Steve Kittelsen <sak1@delphi.com>
Message-ID: <ZC35zAT.sak1@delphi.com>
Source record: 114372

I would use the tuner to feed my scanner. I could lock the prescaler output to a crystal and control the frequency that way. Even with a manual tuning control, you can listen to SCPC from satellites. All you need is a satellite tuner and a scanner that can tune the output IF from the tuner. I've done this and it workes fine. Since the LNB drifts, there is mot much sense in making a very stable tuner. I would receive the 1691 with the tuner and feed the signal to my scanner. That should work also.

A tuner that goes up to 1750 MHz (European type) would cover GOES, so if anybody has one for sale, please let me know. Any IF is fine.

475. The ULTIMATE in long distance QRP (long)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-04 03:12:36 UTC
From: walker@opus.hpl.hp.com
Message-ID: <D3GGx1.88L@hpl.hp.com>
Source record: 114374

It should be possible to reliably communicate around the world using a system similiar to those used to communicate with space-probes.

I'm thinking about taking the idea of coherent CW to the extreme limit. The lower your bandwidth of information, the better S/N you can get. So.... rather than sending 10WPM, I'm willing to send *1 bit/half hour*.

The question is: "how much coding gain can we get in such a system", and how would you design it?

One bit/half hour is completely useless, you say.

Not really.

With a smart microprocessor, one bit of information can trigger a host of activity. Also, if you have an on-board timer at your receiver, you can send multiple messages by sending your bit at the right time of day.

If you only needed to send 12 different messages a day (say to maintain a remote instrumentation site in Alaska), then you could send them by timing your transmission according the following schedule.

```
time meaning
---- -------
1-2am power down instrumentation package
3-4am power up instrumentation package
5-6am switch to program "A"
7-8am switch to program "B"
...
```

People have commonly done such a thing to send one bit of info by ringing the phone. (My grandmother used to tell my parents that she had safely arrived home from her visit by simply ringing our phone once...)

Now, what would be the best system to send such a bit? Two ideas:

1) It should operate in the HF band. Perhaps somewhere near 10MHz (WWV always seems pretty reliable).

2) Correlative coding should be used to reject noise. (essentially a use of spread-spectrum in a band-limited channel).

For simplicity, I'm assuming that the receiver and transmitter are aligned in frequency to 50ppm (garden variety XTAL tolerance). If we send a CW signal, at one random pulse per second, then we can send about 1e6/(50*10)=2000 bits before our receiver will drift 10% out of bit synchronization with the transmitter. This allows us to average 2000 bits to reduce the channel noise by 10*log(2000) = 33dB.

I'm thinking of a receiver with about 700 Hz IF BW (to tolerate the 500 HZ maximum crystal offset at 10MHz), and an integrate-and-dump detector operating with a 1/3 second integration time. This guarantees that at least one of the 3 integration bins/bit will stay in alignment with the transmitter signal over the entire 2000 bit transmission time. (thereby avoiding a complex bit-sync algorithm)

The integrate-and-dump detector would average the total RMS power in the entire IF BW over each 1/3-second integration time.

The transmitted signal could be a 127 bit PRBS signal, repeated somewhat more than 2000/127=15 times. (If you were worried about FCC restrictions on PRBS keying, then just make a plain text CW signal that is 127 "dits" long, and has 50% duty cycle and a good auto-correlation - something like "DX BEACON DE WB6GVI DX BEACON DE...".

The receiver would take each output from the digitized integrate-and-dump detector, once each 1/3 second, and store them modulo 127 into digital memories. The following C-like pseudo-code illustrates the idea:
(skip it if you're not into C-coding :-)).

```
---------------------------------------------------------------
double prbs[3*127] ; holder for spreading code

double rx_array[3*127] ; array for incoming data samples
double epsilon = 0.8 ; decay constant (needs to be optimized)
double threshold = ?? ; trigger value (lower is more sensitive)
; higher is more reliable

initialize_prbs(prbs) ; fill prbs array with +/- 1 bits
; corresponding to spreading code
while (true) {

val = get_new_integrate_dump_signal();

; update the receiver storage array with digital lowpassing
index = (index+1)%(3*127)
rx_array[index] = epsilon*rx_array[index] + (1-epsilon)*val

; now check for correlation with prbs pattern...
max_correlation = 0;

for( i=1; i<=3*127; i++ ) { ; for every phase shift
correlation = 0
for( j=1; j<=3*127; j++ ) { ; for every element of the array
correlation += rx_array[j]*prbs[(i+j)%(3*127)]
}
if (correlation != max_correlation) {
max_correlation = correlation
}
}

; if correlation exceeds our threshold, then a
; signal has been received
```

```
if (max_correlation != threshold) {
do_got_signal() ; OK, we've got it!
}
}
```

Of course it is critical that the integrate-and-dump ADC have a resolution greater than 1 part in 2000. Audio ADCs are now pretty cheap and should do nicely with 16 bit resolution: ~ 1 part in 65,000.

Now what is the coding gain for such a system?

We are subject to thermal and atmospheric noise of 10MHz over a 700 Hz BW. The 1/3 sec. integrate-and-dump baseband processing (I think) takes us down to 3Hz effective BW.

The 2000 bit (or maybe ~1000 effective bits due to the choice of epsilon in the algorithm above) gives us a sqrt(1000) coding gain, or 30 dB.

With a 5 ppm, ovenized crystal, we could get 40 dB!

That means that a one watt, single bit system, should perform like a comparable 10KW CW system with a 3Hz BW..

If we used this system with a 1KW ham transmitter (assuming the FCC would allow such a thing) our transmission would be about as reliable as CW sent with 10 Mega-Watts.

How far do you think I could get with two modified 100mW, 49 MHz walkie-talkies, and a DSP chip? Do you think I could make a *REAL SLOW* garage door opener that would operate from the other side of the globe? :-).

Cheers,

No, there's also Cancelmoose[tm] and the advent of other cancelbot style-solutions to the spammers on the net. I agree that peer pressure is not likely to work--as long as a company has the potential to make so much as one sale, he's going to post ads to the net if he has no respect for the desires of the group's readers. I saw a post that suggested creating a group like rec.radio.amateur.ads to have a place where those who desire to read ads can go. But the advertisers wish to invite themselves into our living rooms and shacks, rather than place their ads on our doorstep.

Again, I refer those who feel imposed upon by spam ads to check out alt.current-events.net-abuse for some very enlightening reading, starting with the FAQs there.

Be sure your power supply / cables are delivering the current without a voltage drop. If the adjustments are near the end of their range, you may have to replace that part with a higher or lower valued part to hit the true tuning peak. A manual also helps.

>The problem with QEX is it is so expensive for us in Europe.

QEX recently changed its policy to allow foreign subscribers to
subscribe using surface mail instead of airmail. Agreed, it's slower,
but then again the articles in QEX don't date as much as QST does.

I just had my 2-years prepayment (another way to get things cheaper;
you pay handling costs only once) changed into a 4-year subscription
by changing it to surface.

It is very likely that QEX is not written as one postscript image, i.e.
asking ARRL for a postscript file probably doesn't help much.

Personally I think that the local hamradio clubs might take part in
the distribution of QEX (sending it in bulk to Europe, then
distribute locally, making it even cheaper...

I suspect it was the copper ions, not the iron or chlorine ions, that
killed the tree.

: In my understanding, FeCl3 is not strictly an acid (no H+ ions), but
: rather a salt which contains lots of Cl- ions, which latch onto the
: copper and form copper chloride. That's why the solution turns green.

Well, yes and no... If it's just FeCl3 dissolved in neutral water, it won't
be acid. But you can't dissolve very much of it in neutral water because
even the 10^-7 concentration of OH- ions is enough to start precipitating
Fe+3 ions in Fe(OH)3 muck. So, you add some HCl to acidify the water,
which lowers the OH- concentration and allows much more Fe+3 to dissolve.

By the way, if you have some FeCl3 solution that's getting muck in the
bottom, try adding a little muriatic acid, which is just HCl, to it. You
can get the acid at home improvement places; used to wash masonry work. As
always, _be_careful_ adding acid to anything.

: The safest way to get rid of your FeCl3 is to use it up etching copper!
: The resulting compounds are not nearly so reactive. It may not be the
: fastest way to etch boards, but it's the most "ecologically responsible".
: When the solution is used up, dump it down the toilet and flush several
: times. (and hope you don't have copper drain pipes ;)

Barry Ornitz, a ChemE with Eastman who used to post to these groups, posted
a very good way to get rid of it, if you don't have a hazardous waste place
that will take it nearby. Basically it's to mix it with concrete dry mix,
in place of the water. The lime in the concrete mix will neutralize it,
and the concrete when it hardens will pretty effectively lock the copper
up, according to Barry.

Pieter,

Try DSP Group, Inc. They were advertising last fall the CT8005
"TrueSpeech Messaging Co-Processor." This is a full-duplex
speech-compression chip with 8.5 kbits/sec compressed data rate. They
also offer (but I don't have the announcement sheet handy) a similar chip
using 4800 bps CELP. I was told the chips would cost about $13 in quantity.

DSP Group, Inc. Santa Clara, CA, 408-986-4300. The man I spoke with at a
trade show is Serdar Yurdakul, Director, Computer Telephony, at
408-986-4480, or syurdakul@dspg.com.

Hope this helps. I'm interested in digital voice modes too.

I picked this filter up for a couple of quid at a radio rally. The frequency is 68.545 MHz. I was hoping that it was a roofing filter for an up-converting HF Rx. Can anyone confirm this, and tell me the bandwidth and I/O impedances?

>HF DX.

Well, there are the Ramsey and Hamtronics kits. You may have heard of the problems with Ramsey, but you can get the kit working clean if you have access to a spectrum analyzer and know some practical circuit theory so you can modify the circuitry to work correctly. If you just tune it up for maximum output, the spectrum will look like a comb. But it is a synthesized design (diode programmed), so it is fairly useful once you have it running correctly.

The Hamtronics kits go together pretty well, and are pretty clean, but they're crystal controlled. That's going to limit the usefulness of the radio for general 2 meter hamming. You can all put it on a club frequency, but you won't be able to channel hop without buying a bunch of expensive crystals. They're mostly used in repeaters where frequency agility isn't important.

Ten-Tec Kits has a new 2 meter transceiver that they previewed at the last Dayton. I don't know if it's shipping yet, but it looked like a very good clean design. It has most of the features of the current Japanese radios. It's synthesized, microprocessor controlled with digital readout, and runs respectable power. Ten-Tec has a great reputation, so they aren't going to release a piece of crap.

If you want a scratch design, the Motorola MC2833 makes building a low power transmitter a snap. And they have the MC13135 that takes most of the pain out of building a receiver. If you call and ask Motorola for evaluation kits for these two chips, you'll get a circuit board, a couple of chips, and an application note that'll get you going. (At least you could a couple of years ago, I don't know if they are still offering these kits.) A small power brick IC will boost the signal to a respectable level.

If all else fails, you can go with one of the older Handbook discrete designs. A pair of 12AT7s will get you a 8 MHz oscillator followed by a doubler and two triplers. That can drive a 2E26 output stage. On receive, a 6CW4 preamp can drive a 6AK5 mixer into a pair of 12AT7 IF stages feeding a diode discriminator using 6AL5s and your AF stages can be one of the classic designs using EL88s. I haven't built this design in many years. I expect

some of the tubes will be rather hard to find in quantity today.

> (WWV always seems pretty reliable).

This is the flaw in your plan. You haven't made allowance for the fact
that parts of the globe will receive *no* signal energy during parts
of the day due to the changes in ionospheric propagation. This will
corrupt the bins and degrade your effective SNR, probably to the point
of uselessness. You need to include a propagation model in your code
which will weight samples depending on predicted propagation.

The difference in what NASA does, and what the Lowfers on 160 kHz do,
and what you are trying to do, is that they are using radio paths of
essentially constant propagation. You're going to have to simulate
that constant propagation model by weighting your samples according
to a HF propagation model.

493. HOAX against AmSoft

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-05 21:49:11 UTC
From: amsoft@epix.net
Message-ID: <3h3h4n$sev@grape.epix.net>
Source record: 114394
Cross-posted to: rec.radio.amateur.policy,rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.amateur.digital.misc,rec.radio.amateur.equipment,rec.radio.amateur.misc,rec.radio.amateur.space

I question if the person called bob@texas.net really exists or if it was just a HOAX and a campaign by a spineless internet hacker to damage the AmSoft reputation.

I submit the following information and request that you as an individual test the information for yourself.

On 2/5/95 I did a FINGER on bob@texas.net and received the following information:

>--- Host: texas.net User: bob@texas.net ---
>Login name: bob
>In real life: Robert J. Scott
>Directory: /home/b/bob
>Shell: /bin/menu
>Last login Fri Jan 20 20:39 on ttyrc from sa-pm1.texas.net
>No unread mail
>No Plan.

Take a look at the LAST LOGIN DATE!
(Last login Fri Jan 20 20:39 on ttyrc from sa-pm1.texas.net)
So how is it that bob@texas.net has managed to post so many messages in the rec.radio.amateur.* usenets as bob@texas.net since Jan 20 and texas.net's finger has no record of it?

Take a look how he connected thru TEXAS.NET ON JAN. 20, 95
(on ttyrc from sa-pm1.texas.net)
Is sa-pm1 a code for SPAM?

It looks like the wool has been pulled over our eyes on this story.
Even the FCC records for WY7O don't correspond to the Texas area.
Whoever you are pretending to be WY70 we are onto your HOAX.

FYI, AmSoft has not posted any reference to it's products since January 27th and will not post reference to AmSoft products in the future except for the rec.radio.swap usenet, and in the amsoft signature when responding to usenet messages.

To all readers of the rec.radio.amateur.* usenets AmSoft posts this public apology to anyone that became annoyed by any aspect of the continuing posts by or about AmSoft and its product.

I request that nobody post a response to this article unless they intend for their message to appear in all 7 rec.radio.amateur.* usenets (read header of this message first)

Sincerely,
Pete, KC3TL

Optical models might be a good start, but are likely to be inaccurate
since they assume the scattering objects are very large in terms of
wavelength. My area of expertise is in electromagnetics modeling, so I'm
not aware of any acoustical modeling programs by name. However, I'm sure
they exist, and you might be able to find advertisements for them in
the various acoustical engineering journals. Be aware that these programs
are likely to be tailored to underwater acoustical applications (sonar).

497. Building your own.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-06 00:07:02 UTC
From: N5EM@aol.COM
Message-ID: <950205190700_13819964@aol.com>
Source record: 114398

Dave,

Boy are you in luck. There are probably a dozen companies out there right now selling QRP (low power, under 5 watts) transceivers and accessory kits. Prices run from the simplest at around $50 up to close to $300.

I will forward a list of these companies to the ham-homebrew list for you to look over.

Please make note of one that is highly recommended.

Dave Benson, NN1G designed a rig called the NE40-30 for 30 meters and NE-40-40 for 40 meters. It was recently described in a QST article and is a single board, superhet receiver and transmitter that runs about 1 or 2 watts. When finished you will have a small, QRP rig that can be hauled around in a backpack or briefcase and works off a small Gel Cell for about $50. That is a pretty painless way to start building your own. If you really want to try homebrewing cold-turkey, then I would recommend that you get a copy of Solid State Design for the Radio Amateur, published by ARRL and written by DeMaw and Hayward.

Just remember, building RF gear is not entirely straightforward and if you have NO electronics background, you are stepping out. Consider a kit first, get it built and working, find a local ham who will help you get it working right and you are on your way. What you do not want to do, is spend a lot of time and energy collecting the parts for something, building it, and never seeing it work. Plenty have done just that. Also, find a club that has some builders in it. If the club has a group of QRPers, or better yet, a local QRP club, check it out. QRPers tend to be avid builders of small inexpensive rigs.

Good luck.

Ed Manuel - N5EM

Hank,

I really don't know from the digest I received who wrote the message on advertising. But, there are now numerous retail businesses being run and heavily advertised on the Internet. Primarily, this is being done via "electronic shopping malls" on World Wide Web. I would not appreciate someone dropping in on a list like ham-homebrew and sending me email advertising their product and that is probably what the writer was referring to. Sending unsolicited advertising is in very bad form and would probably draw the ire from the operator of the system.

>mixing products, i.e. so called diplexers.

The diode mixers are sensitive to termination of the IF port (as well as the LO port and, to a lesser extent, the RF port). Using a diplexer is one way to approach the problem, but another way is to use a post-mixer amplifier (sometimes called a post-amplifier) which has good return-loss on the input over a wide range. According to several references, the actual terminating impedance isn't as critical as the termination being non-reactive. So, you really have several options:

1) Use a diplexer as described in several texts. This does require some tuned ciruits, and may allow some higher order responses of the mixer to be poorly terminated.

2) Use a post-mixer amplifier designed for good input return loss. A common-gate JFET, such as a J310, works well in this application. Examples of this approach were published in _Ham Radio_ about 20 years ago. Also useful for this would be a MMIC, like a MSA-1104. Just be sure to use enough gain ahead of the mixer to establish the desired system noise figure, of course balancing this with dynamic range considerations. Another advantage of the post-amplifier is that it can be beneficial for matching to the roofing filter.

3) You may use a resistive attenuator at the IF port. Really! Again, you'll need to increase the pre-mixer gain or accept a poorer system noise figure, but a 3dB pad (-3dB) results in 6dB additional return loss across a very broad range.

It really makes sense to use only enough gain ahead of the mixer to compensate for the losses in the mixer, termination and filter(s).

There's a fair amount of activity on the 1750-meter band using coherent BPSK. It's been written up in the Lowdown, the journal of the Longwave Club of America. I don't have the references at hand, so I can't quote numbers, but fairly impressive coding gains have been demonstrated. This is part-15 operation, limited to 1 watt input to antennas that, by regulation, are very inefficient. There's also lots of QRM.

There's some DSP decoding software that runs on PCs written by VE2IQ that's becoming popular.

kd9jq_95.zip Preamp & Triode amp design, 4 utility pgms

The following utility programs are distributed, courtesy of
KD9JQ,
as FreeWare in file kd9jq_95.zip:

asp_ver4.zip Contains ASP version 4.0 transistor RF preamp
design
program. It requires EGA or higher.

tap_ver2.zip Contains TAP version 2.0 triode amplifier
program for
grounded grid tube RF amplifiers.

utility.zip Collection of 4 programs for matching,
filters, attenuators,
and transistor compression point calculations.
These are:

1 - compress.exe - calculates transistor
compression point.
2 - bbmatch.exe - calculates broadband
matching L/C values vs Z
3 - atten.exe - simple T. PI resistive
attenuator program
4 - filter.exe - calculats L/C values for LPF,
HPF

I have several Motorola HT220s (and a GE and a Maxon) that I
need to get crystals for. Can anyone suggest a place that sells
crystals for a reasonable price? I also need a line on low cost
batteries for the same radios.

Thanks in advance.

506. HELP CHAN. ELEM. ALIGN MOTOROLA MITREK

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-06 20:43:08 UTC
From: sidener@crunch.nuc.umr.edu
Message-ID: <3h61ks$3a9@hptemp1.cc.umr.edu>
Source record: 114407

I am currently trying to tune a Motorola Mitrek radio to the ham band:

The radio is rated for (146-174Mhz)

It was tuned to 168Mhz.

I have successfully tuned the radio and channel element on the
transmit side to 145.290Mhz.

I am having a big problem getting the channel element (not radio)
on the recieve side to resonate at 144.690Mhz.

Motorola does not produce schemaitic of their channel elements
and I have been told that some components eg. caps. must be replaced
in the element to get it to resonate.

Motorola only has one model of channel element for that radio.
(KXN1088A) TX and (KXN1086B) RX

I was wandering if someone has a schematic or conversion chart pretaining
to the channel element alignment.

Obviously, something besides the crystal must be changed to have a range
of 146-174Mhz.

Any help would be greatly appreciated!!!

Thanks,

Scott Sidener N0WFL sidener@umr.edu

A really NEAT solution (er, solid) to the problem. Even though I was
told that you could dispose of exhausted FeCl3 by diluting with water
and flushing down the drain, this method certainly sounds like a much
better alternative.

Thanks.

Source record: 114409

I do not know if you want to go PLL or DDS route. Phase lock loop info can be obtained from Motorola in Schaumburg, Illionois. They have lots of free technical advice, Aplications notes, etc. If you want to go DDS (Direct Digital Synthesis) there is a company in California (I can not find my notes but I think it is called Standard Telecom or something like that). These companys do not offer kits per se but have all parts available to do what you want.

>access to a spectrum analyzer and know some practical circuit theory so
>you can modify the circuitry to work correctly. <snip>
I must have slept through something. What problems with Ramsey kits?
Mine has never given any trouble. A few capacitors were missing and I
had to enlarge the coils in the tx and rx to maximize output power and
receive sensitivity, and tx power has never reached the advertised level
but what do you want for the price? I've marketed kits before myself and
know the difficulty in quality control etc just in purchasing parts for
the kits. The biggest variable in kits is the kit BUILDER. I've never
had one of my kits returned for repair that wasn't butchered beyond
recognition and huge globs of solder all over the circuit board, shorting
traces and parts galore. Few folks nowadays have the background or
experience in good soldering technique nor the time and patience to do a
decent, much less great, job in assembling a kit.
Unless your circuit can be sold by the kazillions so that you can purchase
your parts by the carload it is VERY difficult to market a kit that costs
less than a comparable overseas-assembled factory unit. And, if it has
that kind of demand the folks overseas will be grinding them out in mass
quantities and pricing you into the dirt post haste. I think Ramsey does
a good job for the price. The manuals that come with their kits are
great for learning circuitry and electronics. I'd recommend them to
anyone who'd like a radio that, though not fancy, extra sensitive, selective,
or high powered, works and gives you experience and satisfaction to boot.
Not to mention that once you have it working you are familiar and brave
enough with it to modify it, interface it to a computer, mess around with
it in all kinds of ways. I like 'em.

| Is it possible to make a TNC with a regular modem and some software?

Yeah - just use the modem chip (if it's a 7910/3105 etc). The serial
hardware is useless.

| Packet sounds like regular FSK modem, but are they the same?

No - it's NRZI-encoded HDLC. Async ASCII it ain't.

| Seems a regular modem with "packet software" running would work.

Yes, if you can get straight to the bits without having them serialised
and bracketed with stop/start stuff.

> So.... rather than sending 10WPM, I'm willing to send *1 bit/half hour*.

There are a few important differences in communication with a deep space probe and in communication around the world using tropospheric, ionospheric or EME modes.

When communicating with a deep space probe, the propagation delay is usually well known and the rate of change can be well predicted. The doppler shift is usually quite stable and in any case, it is predictable.

When communicating around the world, the propagation delay can vary a lot with different propagation paths. At extremely low bit rates this is hardly a problem. However, the reflecting/refracting medium is not usually stationary, so you have some doppler shift on the signal. If the medium would behave like a flat mirror, the received signal would be shifted by some amount of doppler shift and it would be easy to compensate for it. The nasty thing is that usually part of the medium is moving towards you, while other parts are moving away from you and thus, you have both positive and negative doppler shifts simultaneously, i.e. there are sidebands around a carrier. In aurora communication and EME (libration fading), the sidebands can be a few hundred or even a few kilohertz wide. For best sensivity, you have to process these sidebands also. If a spread spectrum is used (assuming frequency hopping for simplicity) the signal bandwidth after despreading can still be a few hundred hertz wide during bad conditions while during good conditions, the bandwidth is a few hertz wide.

Garden variety crystals are usuallu specified at +/- 50 ppm, so the
worst case difference between transmitter and receiver is 1 kHz.

> If we
> send a CW signal, at one random pulse per second, then we can send about

> bits to reduce the channel noise by 10*log(2000) = 33dB.

IMHO, using OOK is out of the question, as we would have to adopt similar
principles as in a Dicke radiometer, switching rapidly between the antenna
and a 300 K noise source (a 50 resistor) to compensate for receiver gain
variation. And while the signal strength and band noise constantly varies,
there are a great difficulty of settting the threshold at the final
detection. A much better system is to use some kind of FSK transmitter,
which constantly sends one of two (or more frequencies). If you take
the FFT of the received signal, you can take the _difference_ between
the signal strengths in different bins and thus compensate for the
variation of background noise.

IMHO, it might be easier to first take the FFT of the signal before any
further processing. The doppler sidebands could be easily included
to improve the SNR. This way it would also be easier to extract some AFC
signals to compensate for the crystal drifts during the long transmission
time. Thus, the IF bandwidth could be reduced, when you do not have to
allow for the drift.

: Nah, 10A is the thyristor rating. The 3kV supply is only 1A continuous...
: Actually it's for the EME system and I do have a QRO permit for that,
: not to mention a lot of unavoidable cable loss.

GM4JJJ lives at the other end of our village. It took him years to
get one of those. He just uses a wimpy pair of 4CX250B's but he's been
collecting bits for something meatier over the past several years.....

: Sorry, I missed something out of the previous description of the
: OE5JFL circuit. It is triggered by the voltage drop across a 10R
: resistor between ground and the negative terminal of the smoothing
: capacitor. That's where most of the energy goes.

: diodes ---+---L-----+-------B+ output
: | | |
: Tfmr C Th
: | | |
: diodes---<X>--R-----Gnd

: The inductor is 100-500uH, (10m of enameled copper wire) giving a
: resonant frequency of about 2kHz and a Q of less than 0.25 when the
: thyristors fire.

Ah, that's the key, getting the energy ditched without a ring turning
off the SCRs. In the case of such a turn-off, not all will go off at
once, and this might mess up voltage-sharing arrangements.

: Provided the 10R resistor can handle the peak current, 135J only
: represents the equivalent of 1A for 13.5 seconds, so anything over
: 10W rating seems OK.

10W long term rating, but a very hefty short-term rating.

: Current is sensed by the ground-referenced negative voltage at point
: <X>. This triggers a flip-flop, which turns off the solid-state relay
: in the AC line to the primary and also fires the string of thyristors
: via the opto-couplers. The transformer-triggered circuit would probably
: work, but the trigger points might be dependent on the characteristics
: of the individual devices... and I would like to be sure that the
: circuit will work first time.

I'd probably lean towards firing via transformers rather than
optocouplers, saves the need for floating power sources to drive the
gates, should be more reliable, and easier to construct robustly.

: As Tom, W8JI put it: If it doesn't work, be sure to wear goggles when
: you short the B+, and have a change of underwear handy.

Yup, I read that and agree totally, get neighbours over a decent radius to keep their pets indoors. You'll need tweezers handy for peeling your eyebrows off the ceiling....

: Cheers David, and thanks for the 'Oscillators' chapter in the latest
: ARRL Handbook - like it *a lot*!

Thyristors are fun/challenging. There's an HP modular system that employs power distribution as a 40kHz sine, carefully regulated. It allows transformer isolation of LF common mode stuff, and free choice of power rails in modules. It used a driven, tuned thyristor inverter using thyristors designed for the old "SYCLOPS" TV psu/lineoutput system. I had the job of redesigning it when thyristor stocks ran down. Thyristors have nasty unwanted trigger effects due to dV/dt, temperature, and lunar phase. 40kHz is pushing it for thyristors. I did the honourable thing, bottled out, and used IGBTs ;-)

Glad you like the chapter, it seems to have been well received. I was really worried writing it, I've not had much writing experience, and I was going far over the target length, and I'd chosen a different emphasis compared to previous editions. The book used to throw circuits at people, and I was trying to write pictures in peoples minds to give an insight into how the things actually work, and what compromises are necessary. I notice you're in the credits, too, but I've not yet had a serious read through much of it, so I've not yet discovered what you did. Keep up the good work with the column, the job of spreading simple truth around in areas where complex myths are rampant is beyond value. I can see the RSGB re-publishing them in collection form rather like the tech topics books over the years.

Um, I've just been making remarks on QRO stuff, and 'RJV sometimes reads this group. I'd better exit quietly. no more capital letters or exclamation marks.....

cheers,
david gm4znx

Paul,
I'm interested to know how the sidebands could be *easily* included?
It seems to me that, in general, their correlation with the carrier is
a very complex thing. That is, they may be generated by a large number of
paths. In the case of EME and uhf/microwave terrestrial communication over
non-LOS paths, I think this is the case.
Is there an easy way to remove the spreading caused by these complex
paths?

518. Homebrew 25 Watt HF amp

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-07 16:31:08 UTC
From: sameer.tiwari@syntex.com
Message-ID: <NEWTNews.100.792178781.Postmaster@ptwxa3.Syntex.Com>
Source record: 114417

I have built many HF amps in the QRP region, but I have long wanted to build a 25 watt amp using regular power MOSFETs (IRF 511 is the recommended one due to it's internal geometry) and using power splitters and combiners to make a 1.8 - 30 MHz 100 watt solid state amp at LOW-low cost. (Each 25 W mod should not cost more than 12 bucks).

The problem is availablity of IRF 511 power MOSFET, Radio Shack used to carry them in 1990-91 @ $1.80 a piece, now they don't. Some local electronics supply stores carry it but want $8 or $10 a piece depending on the qty.

I believe there are some stockists on the East coast who sell these for a buck a piece. If someone has a list of these guys please help me out.

Anyone interested in discussing switching power MOSFETs as HF amps

Well the fellow I sold mine to sent me a note complimenting me on
its assembly. He said he thought it was better than most factory
jobs. (I have been working professionally in electronics for
over 30 years, and consider myself a highly skilled craftsman,
even if I do say so myself.) Assembly wasn't the problem. There
were several problems with the design, all of which I eventually
fixed. For one, the output spectrum looked like a comb when the
radio was tuned to anything approaching its rated output power.
It could easily be tuned to 6 watts out, but most of that power
wasn't on the indicated frequency. That was caused by an output
amplifier design with *very* conditional stability. Another problem
was that the radio would transmit while the synthesizer was out of
lock. That's a cardinal sin which puts a "sweeper" on the band that
keys any repeater in its path, and was solved by qualifying the buffer
collector voltage with the synthesizer out of lock line (unused in the
original design) via a keying transistor. Of course the crystals for
the offset oscillators wouldn't come on frequency as supplied. They
could be padded onto frequency, but with a marked reduction in stability.
Replacement crystals were necessary to get the rig to perform correctly.
There was a hard squelch "thump" that needed fixing. Etc, etc, etc.

Most damning, my kit was not an abberation in this regard. Several
locals asked me to look at theirs, and they had the same problems.
And several others on the net have commented about the problems too.
This isn't an assembly issue. But even so, I'd suggest that a kit
meant to be built by the masses should be designed to take that
into account. Circuitry shouldn't be potentially unstable, should
be forgiving of component tolerances, and should have considerable
self-testing features built in to minimize the amount of external
test equipment required (or the advertising and manual should clearly
state the test equipment and expected skill requirements needed to
accomplish the project.)

>Unless your circuit can be sold by the kazillions so that you can purchase
>your parts by the carload it is VERY difficult to market a kit that costs
>less than a comparable overseas-assembled factory unit. And, if it has
>that kind of demand the folks overseas will be grinding them out in mass
>quantities and pricing you into the dirt post haste. I think Ramsey does
>a good job for the price. The manuals that come with their kits are
>great for learning circuitry and electronics. I'd recommend them to
>anyone who'd like a radio that, though not fancy, extra sensitive, selective,
>or high powered, works and gives you experience and satisfaction to boot.
>Not to mention that once you have it working you are familiar and brave
>enough with it to modify it, interface it to a computer, mess around with
>it in all kinds of ways. I like 'em.

Anyone who thinks they can save money by building a kit is just fooling
themselves. As you note, assembled gear is generally cheaper and better
than the kit products, and certainly modified commercial surplus gear
will be both cheaper and better. Ramsey is sadly about as good as it
gets in the kit department since the demise of Heathkit, but that's
not high praise. A kit assembled according to instructions should work
according to specifications. Ramsey's two meter kit doesn't.

That doesn't mean you aren't getting value for your money, however.
The kit is a challenge to your skills, especially the part where you
find and fix the design mistakes. And, in this day of few central
parts sources, buying the Ramsey just for the collected hardware it
contains as a starting point for a project is not completely out of
line. The aggravation you save acting as purchasing agent for all
the odd parts is worth something.

I'm not suggesting that a kit builder not buy Ramsey kits, but I do
suggest that one should *expect* to have to modify this design to
have a radio that's both legal and usable. Access to a spectrum
analyzer is a minimum requirement for getting this thing to work
correctly. Few kit builders have the test equipment needed to make
this kit transmit legally, and we don't need a lot of trashy signals
on the band. There are enough pager spurs already. (To be fair,
Ramsey appears to have revised this kit from the original model
I built. Some of my complaints may have been addressed. I haven't
built or tested a recent example. However, having been asked to
check a factory built Ramsey communications monitor against my

IFR and Tektronix spectrum analyzers, I'm dubious. That thing is trashy too, with several design errors.)

The Hamtronics kits are better in this regard. They usually tune up *clean*, if not with very spectacular performance, using only simple test equipment. And I have hopes that the Ten-Tec 2 meter kit will be properly designed. It certainly looked good from the prototype I saw.

Source record: 114323

I have built a little yagi system, and all works great. The yagis are
well tuned and are quite broad-band. But the optimum spacing?!

Yagimax lists the best to be 0.5 wavelenght (100 centimetres) but all
other theories fight against it. The physical data for the yagis are:
boom 2.5m, elements insulated from boom and are above it, 6 elements.

Can you tell, bu theory or by experience, how much the spacing should be.

Qualcomm and Analog Devices both have demo boards which can qualify
as "kits" for their parts.

Check with Novatech Instruments for DDS kits. See .signature below
to see why I am not an unbiased unobserver.

Source record: 114327

Hi,
I'm looking for programs or pointers to help with the design of eliptical band-pass filters for the HF regions. I have similar programs for the 7 element Chebyshevs, etc. but I really want to model the 5 element (7 component) eliptical filters. I have looked at the Amateur Radio Handbook(s), but would like to understand the math behind the design, rather than looking up the values and extrapolating from a table. Anybody else brewing their own filters for rigs? Any pointers would be appreciated. So far, I have not found an ftp site with any programs for doing this.

P.S. I used to be an S transform and Laplace kind of guy, but have forgotten most of what I learned, hence my desire to understand the math again.

Thanks,
Ed Burress

Thought this might be of interest to those looking for kits. I am still going to post a list of suppliers for builders to have, but this are typical of some of the QRP oriented kit reviews that are posted on the QRP-L list. If you find this interesting and useful, let me know and I'll get some of the others and forward them to the ham-homebrew.

Hi...

As a result of the article in QST, November 94 and some of the comments on the QRP-L mailing list, I decided to order the 30M version of Dave's (NN1G) transceiver. I sent my money order in in late November and received my kit on the Dec 29.

I opened the large envelope and found a PCB (silkscreened and solder masked), manual, bag of parts and 4 small envelopes with the additional parts that could be easily confused if mixed in with the rest. One envelope had the FTXX-43 cores and another the FTXX-61 cores (these are not color coded so are difficult to tell apart). Another envelope had the wire for winding the toroids and the zener diodes (taped to a sheet and labelled).

I read through the manual to get an overview before starting to build the kit. I followed the described sequence for putting the parts on the board. The quality of the board was very good and all the parts went on without any trouble, with one exception - the small variable capacitors had one lead wider than the other and wouldn't fit through the hole. I had to enlarge two holes on the board.

Annoyance number 1 was the parts list/silkscreen. The parts list doesn't give values for the resistors as these are marked on the board overlay in the manual, but parts designators aren't marked on the silkscreen. There was also one error on the silkscreen - C1 is labelled

as C2.

Annoyance number 2 - the IC's were loose and wrapped up in a piece of aluminum foil - not in foam. Two of the IC's had the pins bent right over. This can be a real problem if you're not very careful straightening them out.

The board took about 4 hours to get assembled. Next I had to make a trip to Radio Shack to get the potentiometers required for the tuning and RF gain control.

I did a visual inspection of the board after cleaning it with flux remover, measured the resistance from the IC power pins to ground to make sure there were no major shorts, plugged in the IC's and head phones and turned on the power. No smoke!

The instructions say to use your main HF rig with the power cranked down into a dummy load as a signal source to align the receiver. Having just aquired a signal generator good down to .1 uV, I decided to use it. I hung a short wire off the antenna lead of the transceiver and put a clip lead on the sig. gen. output. I swept the generator from 9 - 11 MHz until I heard the signal in the qrp rig. The receiver worked!

Using my TS430 receiver I confirmed the generator signal - 9.7 MHz. I removed 1 turn from L1 and this put me up to 10.107 MHz. I added a 27pF NPO across L1 as indicated in the instructions and got it to tune 10.1 MHz at the low end of the tuning range.

I followed the instructions to peak up the TX filter but when I tried to adjust R6 to bring the RF up to 1.5W, all I could get was 200mW. With power meter in line, I keyed the TX and adjusted the filter again. I was able to get 1.5W but I lost the sidetone. A quick check with the scope showed RF in the audio. I suspected pickup by the audio amp leads, so I moved them about, but the problem persisted.

I sent an e-mail to Dave, NN1G asking about this problem. While waiting for a reply, I added RG174 from the board to the ANT connector, and ran twisted pair for the key and audio out lines. This time the rig peaked right up at 1.5W and the sidetone was fine.

The next day I got a reply from Dave indicating that RF pickup was the likely cause... thanks Dave - it's great to be able to get assistance direct from the designer!

The receiver works quite well (once I realized that 30M is dead in the evenings at this time of year!). The 2 crystal filter isn't as good as the filter in my NORCAL40 and I can hear a bit of the other sideband when tuning through strong stations, but just barely. Tuning is smooth, although non-linear, but this is expected with a simple varactor circuit.

The lack of AGC could take some getting used to, but being used to Direct Conversion receivers this wasn't really a problem for me - and

there's none of the problems associated with audio-derived agc. I used headphones with an in-line volume control to make life a bit easier.

About the biggest complaint I have with the kit is that the designators for resistors aren't shown on the parts overlay, they're shown by value. The other components have the designators shown. I was trying to locate a specific resistor to take some measurements. I found the one I wanted on the schematic, but had to trace it back from a labelled component. A minor annoyance.

Would I recommend the kit?

You bet! All of the parts were there, it went together easily and worked right off (once I cleaned up my act with cabling), and it works well.

You have to pay the extra cost of the 2 potentiometers, an antenna connector and connectors for a key and headphones, plus a case. This could boost the cost by about $25 if you need to buy them, but it is still one of the least expensive kits you can get, and you can customize the case the way you like.

Now I'm just waiting till I have some time during the day, when 30M is active so I can have some QSO's!

... Dave

Erik, the "rule of thumb" I've read in and believed in is found in the
old ARRL VHF handbook. However long your booms are is a good basic
stacking distance.... you want their patterns to combine and not take
away from each other. Theoretically the farther apart you stack them the
higher the gain but the pattern really gets weird if you separate them too
far.

Sorry, bad choise of words. I should have said: In frequency domain,
it is easier to handle the noise sidebands than in time domain.

I was thinking of a system like this for ultra low speed reception:

- use 1 to 2 kHz IF bandwidth and digitise the signal
- take FFT a few times a second and store spectra
- try different drifts by shifting the spectra and sum them
- locate the signal frequencies (FSK) from the best sum spectrum
- fine adjust the drift and calculate new sum spectrum
- determine the spreading of the both FSK tones
- use this bandwith for further processing
- establish bit (chip) synch
- do normal spread spectrum processing

With enough memory to store a few minutes of signal or spectra, there is
no need to send long preambles to synchronize the receiver, since as
soon as the receiver has determined the actual drift and tone spreading
from the beginning of the message, the receiver can quickly catch up.

Other statistical analysis could be done to the spectra e.g. to detect
local interference (with different statistical properties than the
wanted distant signal).

In radio astronomy (and appearantly also in SETI) much work has been done
to detect weak (more or less) broadband noise sources and also to keep
out any man-made nose sources from the measuremnts, so I suggest that
if someone is seriously trying to build an ultra low speed link to
check the modern radio astronomy litterature.

> That is, they may be generated by a large number of

No, I don't know how to coherantly add these signals together.

> Is there an easy way to remove the spreading caused by these complex
> paths?

With only a few discrete paths and sufficiently high chip rate, you could
lock multiple "receivers" to each discrete reflection and add the baseband
signals.

As strange as it might sound, the received EME signal has similar
properties as the the signal from a car moving on a street received
on a fixed base station. As there is usually not a direct path between
the car and the signal propagates via reflecting surfaces, some are
in front of the moving car and some behind it. Consequently, different
reflections are getting different doppler shift broadening the received
spectrum. This random FM is detectable at road speeds above 1 GHz.
A similar spectral broadening is experienced by the EME signal reflected
from different (east and west) parts of the moon moving towards or away
from us due to lunar libration.

A good treatment of random FM can be found in Jakes William C. jr.:
Microwave mobile communications (New York, Wiley 1974). There was
also a description of a complex system to combat random-FM with
an unmodulated pilot tone close to the actual signal, but I did
not study it in more detail.

: I only do listening, which means I don't have a transmiter to check the SWR of
: the antenna. (at least I don't think I can with my current equipment) This
: is the root of all my problems because the ARRL and most other books assumes
: you can find standing waves on the antenna.

There is a device known as a noise bridge that can be used in conjunction
with a receiver to measure impedance. The receiver is used as a null
detector--it indicates that the bridge is balanced.

: I don't understand the purpose of the Gamma rod or the T rods shown in figure
: 37, 17-17 of the ARRL. (wait: are they an easy way to keep the distance x (
: the space between the antena and the line) constant? If so should the rod
: come to the centre of the antenna? Does the total length of the rod matter?
: ie. The book refers to the rods as being adjustable, does this mean the length
: of the rod is adjustable, or the position on the antenna is adjustable?)

You can vary all these factors to obtain a match. The process is largely
experimental--the calculations are a very rough starting point, in my
experience. However, I've not been able to replace the equations with
better ones.

The easiest way to match a yagi is to split the element and use a
transmission line matching section to match it.

I'm in the process of making my own connectors for 75 ohms CATV hardline. I want to use threaded copper plumbing reducer fittings. Three quarter inch fittings are the right size. At the "reduced" end I silver solder a barrel connector. The center pin gets attached to the center conductor of the cable.

There is one problem and that is that the fittings and the hardline are of dissimilar metals (Al & Cu). I understand there is a compound that is effective in preventing corrosion/oxidation and the accompanying "diode" effect that develops due to the dissimilar metals used.

Does anyone know where I can find dielectric grease, which is designed for just this type of application.

Many thanx for taking the time to read this. 73 de Walt - K2WK

How bout a led attached to a D sized alkaline battery? Tell him to watch it and let you know when it goes out? That oughta keep him busy for a year or so.
My Dad made me something he called a blinky when I was little using a NE2 Bulb you could do the same with LEDs and a 555 timer

How bout making light with no electricity? Run a little saran over a flouresent bulb in the dark.

The lod knife switch and dry cell and light bulb make for hours of fun.
How bout a little DC motor? With a Mesmerdisk on the spindle?

Build that crystal set!

Fun with sparkcoils? Big sparks! Burning wood.

Look in the kids section of the library under electricity Lots of scout books and stuff.

And if all else fails tie a 1" square of red cloth to the end of a string. Tie about 5 ft of the string to the end of a stick. Dangle the cloth in front of a frog and he will try to eat it! And then he can't spit it out cuase his mouth is sticky. You can jerk him from the pond and catch him. Now this has nothing to do with electronics but 5 year old boys love doing it.....and so do I!

: then would 3dbm be 2mw @ 50 ohms. I'm interested
: in computing the rms volts to develop n-dbm into 50
: ohms for the mixer i'd like to use.

Yep. Or you can just calc the volts for 1mW @ 50 ohms = .2236VRMS, and multiply (or divide for negative dB) that voltage by 1.41 for 3dB or 2 for 6dB or 3.16 for 10dB or 10 for 20dB. So +46dB would be *10, *10, *2, for 20+20+6dB. And +17dB would be *10, /1.41 for +20-3dB. So +17dBm is .2236VRMS*10/1.41 = 1.58VRMS. These rules of thumb can be useful when you don't have a calculator (or table of logarithms! ;-) handy.

:
: >Can you tell, bu theory or by experience, how much the spacing should be.
: >Replies via e-mail to lakki@krk.fi
: >
: >/Erik
: Erik, the "rule of thumb" I've read in and believed in is found in the
: old ARRL VHF handbook. However long your booms are is a good basic
: stacking distance.... you want their patterns to combine and not take
: away from each other. Theoretically the farther apart you stack them the
: higher the gain but the pattern really gets weird if you separate them too
: far.

The optimum stacking distance depends on what you want from the array.
As you move the antennas farther apart, the gain increases and goes
through a maximum; but you always get extra sidelobes due to stacking
antennas, and these will continue to grow as you increase the spacing
(as Jim says, the pattern gets weird).

If you want maximum gain, you'd stack the antennas farther apart than
if you want to keep a clean pattern.

How these two factors balance out will depend on the actual antennas.
There is NO rule of thumb that is valid for all antennas. The old
ARRL VHF Handbook says: "As a rule of thumb, the minimum desirable
spacing is one-half the boom length..." - but that was written more
than 30 years ago.

That book used to be my "VHF bible", and it still contains some good
information; but I think Ed Tilton would be shocked if anyone was still
following his dictates blindly, and ignoring what we have learned since.

As always, the difficulty is to decide which pieces of old knowledge to
keep, and which to discard. Most 1960s yagi designs and the "rules"
about stacking fall into the latter category.

If you have Yagimax or any other program that will make computations
of the patterns and gain of your actual antennas, believe the results.
Computer programs aren't perfect, but in this area they are better than
any gain and pattern measurements that we amateurs can make.

Kein{nen Paul (k23690@proffa.cc.tut.fi) wrote:

: The nasty thing is that usually part of the medium is moving
: towards you, while other parts are moving away from you and thus,
: you have both positive and negative doppler shifts simultaneously,
: i.e. there are sidebands around a carrier.

Thats why I proposed a broadband IF power detector. The sidebands are
supposed to fit within the proposed IF, and so are properly accounted
for. The trade-off with my simple scheme is the extra atmospheric noise
that is allowed in by the wider BW.

: > For simplicity, I'm assuming that the receiver and transmitter are
: > aligned in frequency to 50ppm (garden variety XTAL tolerance).
: Garden variety crystals are usuallu specified at +/- 50 ppm, so the
: worst case difference between transmitter and receiver is 1 kHz.

I'm assuming a precision transmitter and a cheap, in-the-field receiver.
That's how I got the 500Hz variation instead of 1kHz.

: > If we
: > send a CW signal, at one random pulse per second, then we can send about
: > 1e6/(50*10)=2000 bits before our receiver will drift 10% out of bit
: > synchronization with the transmitter. This allows us to average 2000
: > bits to reduce the channel noise by 10*log(2000) = 33dB.

: IMHO, using OOK is out of the question, as we would have to adopt similar
: principles as in a Dicke radiometer, switching rapidly between the antenna
: and a 300 K noise source (a 50 resistor) to compensate for receiver gain
: variation. And while the signal strength and band noise constantly varies,
: there are a great difficulty of settting the threshold at the final
: detection. A much better system is to use some kind of FSK transmitter,
: which constantly sends one of two (or more frequencies). If you take
: the FFT of the received signal, you can take the _difference_ between
: the signal strengths in different bins and thus compensate for the
: variation of background noise.

I think On-Off-Keying (OOK) works fine. I am not trying to set a
threshold for any given bit. I only linearly integrate them over time.
The rapid switching is done by comparing the average of the Off
intervals (pure channel noise) with the average of the On intervals
(noise + signal).

The idea is to chop the incoming signal at a rate that is faster than
the receiver gain variations. The bins that contain signal power get added
into the integrator, while the bins without signal power get subtracted.
With a 50% duty cycle on the spreading code, this causes the

uncorrelated background noise power to decrease as sqrt(N), while the averaged signal power component grows as (N). This gives a S/N improvement of N/(sqrt(N)) = sqrt(N). This is not affected substantially by slow gain changes. An appropriate AGC with a time constant of several bit times is sufficient to stabilize the system gain.

I do agree, though, that FSK would be a better use of the transmitter power. You get twice the transmitted energy since you never turn the transmitter off. I would implement this as two IFs (one for the upper tone, and one for the lower tone). Each IF power detector would be correlated as originally described: one with the same spreading pattern, and the other with the complement of the spreading pattern.

If you carefully read the pseudo-code in the original post, you'll see that the only clever bit is a way to avoid a-priori synchronization of the despreading code. By averaging the power-samples (modulo the sequence length) into a RAM, you can defer the de-correlation until later (when the SNR is greatly enhanced by the averaging process).

: IMHO, it might be easier to first take the FFT of the signal before any
: further processing. The doppler sidebands could be easily included
: to improve the SNR. This way it would also be easier to extract some AFC
: signals to compensate for the crystal drifts during the long transmission
: time. Thus, the IF bandwidth could be reduced, when you do not have to
: allow for the drift.

This would be a good (although complex) way of reducing the effective power, and would probably out-perform my simple power-correlating proposal. There are several algorithms (extracting AFC, drift compensation, sideband identification vs noise, etc) that need more elucidation before it would be a realizable system.

Jeff...
Currently the 6 mtr. world is handicapped by a lack of gear...small and portable and ssb/cw would leave only th Yaesu FT-690...around $700 new and $400 used. Or the Kenwood TS-60...about $1000 new...how about building or buying one of the little QRP rigs for 20 mtrs., (MFJ comes to mind) and then adding the Ten-Tec 6 mtr. transverter kit...it's only $95 and works great...you will only get around ten watts out for the 5 you put in, but to a small beam should be the ticket...just depends how much stuff you want to include on your trek. I just found a 690 used here in the internet and can't wait to get it and use it for much the same thing.

I used to use it many years ago. It works a lot better if you add some
salt. The downside is that chlorine gas is given off. I remember reading
that mercuric chloride is even better than salt, but that is *very* toxic.

I would use it in preference to FeCl3 if I could still get it.

I have a related request. I would like to build a 2m to 10m receive converter. I have already build and tinkered with a hamtronics one that works, but I'm not satified with the performance. I am particular disappointed with the fact that the LO is highly present at the antenna, about -35dbm according to a HP spectrum analizer. Since I am not an RF engineer, I do not have the ability to design one (probably not the time either), can someone point me to a good design or kit? I have envisioned one with a good RF amp, a good mixer to solve the above problem, and an IF amp to solve some of the problems that Dana mentioned.

Thanks

DPY>

David
Check out a company called Ramsey. They have a number of kits you
can build including a mini stereo FM tranmitter that puts out about
100mw. The advertise in all the Ham Radio Journals along with
Popular Electronics and a few other electronic mags. Good Luck.

... Back up my hard disk? I can't find the reverse switch!

A 20 meter C.B. is possible, I have done it with a Uniden PC122 ssb cb. Lots of work and not for
the beginner, but it is possible. I think 15 and 40 meters are possible also. 80 meters would
require some major engineering.

Hi, Johann

The E310 is an old n-channel JFET made by Siliconix.
They stopped production 15-20 years ago. The replacement
for that type is J310 made by the same company.
I remember that your device is housed in a ceramic
package with a black top, while the new version are
in TO92 black plastic case. A S S U M I N G analogy
in pin counts in both types pin numbers looking from
bottom left to right is 1 2 3,when leads oriented
like a roof (triangle up)than:
pin 1 is gate
pin 2 is source
pin 3 is drain according to my data sheet of J310.

Consumer Credit Advocates, PC
11 Pennsylvania Plaza, Suite 2101
New York, NY 10001
(212) 629-5261 (telephone) (212) 629-4762 (fax)
E-MAIL: ccapc@cyber.sell.com

Our LAW FIRM offers direct guaranteed effective credit restoration services by experienced attorneys. THIS IS NOT A DO-IT-YOURSELF KIT.

What can we do?

We have successfully facilitated the removal of Late Payments, Charge-offs, Foreclosures, Repossessions, Collection Accounts, Loan Defaults, Tax Liens, Judgments and Bankruptcies from our clients' credit reports. WE GUARANTEE THAT YOUR CREDIT CAN BE RESTORED!!!

Who needs our services?

Anyone who has experienced the inconvenience and embarrassment of being turned down for a credit card, a lease or a purchase of an automobile.

Anyone who is unable to buy the house of their dreams due to denial of a mortgage application or who has to pay thousands of dollars more in mortgage interest than someone with good credit.

Anyone who has been turned down for a job or promotion due to derogatory credit items on a credit report.

Anyone in business who has lost a deal because a person or firm wanted to see his/her credit report before doing business.

Anyone who has been unable to establish credit.

THE FOUR GREAT MYTHS OF CREDIT:

Myth #1: It is illegal or immoral to have your credit report cleared.

Fact: It is not illegal nor immoral. In fact, that is what the Fair Credit Reporting Act is all about. The act was enacted by Congress in 1971. One of its purposes as to give consumers the protection of the law and to help guard against

any unwarranted invasion of a consumer's right to privacy.

Myth #2: The information on a credit report cannot be changed.

Fact: Actually, the opposite is true under the Fair Credit Reporting Act. Federal and State laws require that items be removed if they are not 100% accurate or cannot be verified in a timely manner.

Myth #3: It is impossible to get a bankruptcy off a credit report.

Fact: Bankruptcies can come off credit reports like any other derogatory item. The nature of the derogatory item has nothing to do with its removal under the Fair Credit Reporting Act.

Myth #4: Credit Reporting Agencies are empowered with some kind of governmental authority.

Fact: Absolutely Not!! They are simply large corporations whose primary goal is to make a profit like any other business.

If you have ever applied for or received credit, a file exists in one or more of the credit bureaus. These companies collect, store and distribute as much credit information as they can find, retaining negative information on a credit report for 7 to 10 years. This information is evaluated by potential creditors to determine your credit worthiness.

Credit reporting agencies are in business to protect the interests of the creditors. the LAW FIRM's goal is to help and protect the individual consumer from inaccurate credit reporting.

The president of our LAW FIRM has been practicing consumer law since 1984. The staff of our firm has successfully processed, disputed and challenged thousands of client credit reports.

Our legal fee is based o the number of negative items that appear on a client's credit reports, issued b the three national credit bureaus. Our retainer agreement offers a MONEY BACK GUARANTEE stating that if any negative item is not deleted, upgraded or corrected from a client's credit file, it will give the client a full refund for that item or continue to process the client's file at no additional fee until that item is

corrected, upgraded or deleted. THE ONLY THING YOU HAVE TO LOSE IS YOUR BAD CREDIT!!

PLEASE CONTACT THE LAW FIRM AND LEAVE YOUR FULL NAME, MAILING ADDRESS AND TELEPHONE NUMBER SO WE MAY FORWARD FURTHER INFORMATION AND INSTRUCTIONS TO YOU ABOUT OUR SERVICE.

Moto also has an evaluation kit for their 1.1 Ghz PLL...MC145190EVK
and MC145191EVK. I called and checked on the price once, they were
a bit steep for me...about $400, as I recall, for a board with
their synthesizer chip, a VCO and an interface to a PC printer port.
You also get some nifty software to run the thing.

There's a picture in the Communications Device Data Book DL136/D Rev 3.

I'd buy one if they dropped the price to about $100, but I guess it's
the VCO that costs so much. Oh well :-(

No, you don't want dielectric grease, which is an insulator. What you
want is a product called NoAlox, which is a conductive penetrant and
protectant sold at any electrical supply house. It's used where aluminum
wiring, such as power entrance cable, is connected to the copper connections
of a meter box or service panel. A lifetime supply (for hams) is only
a couple of bucks.

In chapter 21 of the ARRL Handbook (I'm looking in the 1992 edition)
there is a 2 meter transverter project. Simply delete the transmitting
portion, and you have a good receive converter project. GASFET preamp,
crystal LO chain, SRA-1 mixer with discrete diplexer, and 28 MHz post amp.
I'd be tempted to replace the discrete diplexer and post amp with a
MMIC and BPF, but the given circuit should perform well.

The 2N3055 is easy. It's THE ubiquitous power transistor, and everybody should have them, including Radio Shack. The GE devices cross-ref to (i.e. are <= to) a complementary pair (-18 is NPN, -21 is PNP) for audio or video (100 volts, 1 amp, 100 MHz). You could try the NTE/ECG subs (128 for -18, 129 for -21), or something along the line of the MPS-U01/MPS-U51 pair (only good to 80 volts, but easier to find).

My understanding is that ammonium persulphate requires a catalyst to work properly. I recall having difficulties with it. Some places have indeed sold it.

As an alternative, you might consider cupric chloride. Barry Ornitz posted a tickler about it a couple years ago. Basically, etching copper creates more etchant. You need to oxidize the cuprous to cupric, but that can be done with patience by bubbling air through it. And you need to keep the acidity correct with hydrochloric acid. Probably the worst part for a home shop is figuring out how to measure the concentrations. Barry recommended an out-of-print book on electronic prototype construction as a good source of info on this method, and backed it up with personal testimony.

>73, K7ITM

Another alternative is to use electrolosis for your etchant. Simply
use a a standard exectroplating bath (copper sulphate with a bit of
sulphuric acid)) to remove most of the copper. Islands may form at
the very end which can be cleaned up with standard etchant, but tilting
the exectrodes, you can encourage the copper to be etched from the far
side of the board to the place where the power connection is made.

The beauty of this approach is that the only 'waste' is the extra copper
on the other electrode, the solution lasts `forever'. Side benefits
are that the speed of etching is not a function of temperature as it
is of current, so it is highly controlable.

About 10 yrs back, I had just made a PCB for a RC reciever for a model car and after 5 hrs of work realized I was out of FeCl3, so (DO NOT USE THIS METHOD NO3 poisning may occur) I used HNO3 instead, it worked fine and the pcb was etched in 1-2 minutes flat and then the acid starting eating into the Nail polish(which I used for masking) and I had to hurriedly wash it off with lots of soap(alkali- to neutralize the acid). The end result - I got the PCB, but the copper markings were kind of rough, but I got the PCB and the RC reciever still works.

Thinking back on the incident, it was really stupid to do that and I never did that again(always have a stock of FeCl3)

I have built several 40 watt amps using IRF-531's and IRF-530's. They work fine on 80,40, and 30
meters. On higher frequencies they begin to loose gain somewhat. It is still possible to use them
as high as 10 meters but they require higher drive. This is the drawback to using them in a broadband amp. I have also used the BUK-455 mosfet with similar success. Most of the amps were mono-band and tuned circuit variety.

Dana Myers (myers@Cypress.West.Sun.Com) wrote:

: The diode mixers are sensitive to termination of the IF port (as well as
: the LO port and, to a lesser extent, the RF port). Using a diplexer
: is one way to approach the problem, but another way is to use a
: post-mixer amplifier (sometimes called a post-amplifier) which has
: good return-loss on the input over a wide range. According to several
: references, the actual terminating impedance isn't as critical as
: the termination being non-reactive. So, you really have several
: options:

: 1) Use a diplexer as described in several texts. This does require
: some tuned ciruits, and may allow some higher order responses of
: the mixer to be poorly terminated.

A band pass/band reject diplexer may do a better job of terminating
the responses than a high pass/low pass diplexer. A lot tougher to
tune up, though it isn't that hard with a good sweep setup.

A broadband resistive termination isn't the best theoretical
solution. Ideally, you can return the unwanted mixing products
with the proper phase to actually enhance mixer performance.
The resistive termination may be the best practical solution
for most people.

However, since the poster was designing a single band 2 meter
SSB transceiver, for many years the Handbook has had some rules
of thumb for reactively terminating VHF diode doubly balanced
mixers (written by K1AGB initially in March 1975 QST, though
I think we took it out of the 1995 Handbook to make room for
newer material).

|>
|> |>
It rather depends on what you mean by optimum. Front to back and sidelobes (for EME) or gain (for contests).

There was a publication called wires and waves by Practical wireless that has some useful information taking into account the radiation pattern of the antenna. With 2 6 elements, spacing them more than 1.5 wavelengths apart would be OK. Remember that the top antenna is higher up, so if you are not on a mountaintop a higher close spacing is better than a wider spacing with the bottom antenna nearer the ground.

I've put a logic analyzer on the bus between the head and the box, and it's very indecipherable. I spend 3-4 hours trying to figure something as simple as a single button press. I've got *no* idea what's going on with this puppy. Someone had a mod file that explained how to control the RF decks directly. They basically use a big shift register, and set bits for whatever function you're trying to do. But as for the head to box connection, it's got me beat. (*Noooooooo.... It couldn't be a simple async protocol so you could just connect the UART on a PC... Noooooooo. They had to make it wierd*)

>the VCO that costs so much. Oh well :-(

I've been experimenting with the MC145170 PLL (good to at least 160MHz)
and it seems to be pretty darn good (i.e. works as advertised).

A buddy and myself are working on building up some 900MHz+ gear. We've
picked a handful of the MC14519x and MC14520x parts for
experimentation. No, we didn't get the eval kit. Yes, a decent VCO at
900MHz+ is not trivial (for that matter, a decent VCO at any frequency
isn't trivial). For the moment, we plan to build the VCOs, afterall,
we're experimenting and learning. But, if someone can point me at
sources of economical VCOs in modular form, like would be used in
cel-tels or Part 15 devices, I'd love to check them out.

Message-ID: <950210145317_18160129@aol.com>
Source record: 114225

Walt, do you really want dielectric grease? Usually, between dissimilar metals like copper and aluminum, one uses a conductive grease, like the stuff called NO-OX. That is a brand name conductive grease that is loaded with carbon, I think. Go to your local full service hardware store and go to the electrical department. This is the stuff you use if your house was build by cheap idiots a few decades ago using aluminum wire with regular copper and brass based switches and outlets. You put this stuff on to prevent a build up of corrosion and, ultimately, spontaneous combustion in your walls.

I have used it (and a variety of similar products under various names) on the sliding surfaces of aluminum tubing to keep the "similar" surfaces from forming al-ox, that dry white powder that forms down here near the Gulf of Mexico and effectively welds two sections together.

Just remember, you want a good fit of the separate pieces, then only a thin coat of this stuff between them. Mechanically secure connections are still very important. Good Luck.

Can anyone give me a suggestion as to a good frequency detection chip with a very fast response time ? Not DTMF (none of those IC's have a response time of > 20 msec, even at 4 bits per signal that's only 200 bits/second)

I am attempting to build an FSK/MSK digital datalink in the 80 MHz "free" band. I need a reponse time in the order of 1-5 milliseconds. Of course, a faster reponse time would always be better.

Anybody have a IC that fits ? Or an old-fashioned analog circuit ?

Mini-Circuit Lab may have the VCO that you want, they are now advertising a series of VCO modules with low phase noise. They cover from something like 20MHz to about 900 MHz I believe (you have to check their ad). The prices are quite reasonable, they quoted me about $19 a piece with a minimum order of $50. Seems like a good deal to me. BTW, most of them claim a tunning range of 2:1 from about 1 to 15V.

I don't know if this is the best place to post this question, but
here it is...
I have a Drake TR-4. I've noticed that with the XMITR GAIN and RCVR GAIN
controls advanced, anything that is picked up by the mike can be heard
through the speaker while the radio is in recieve mode. In fact, if the
RCVR GAIN is advanced too mcuh, feedback occurs. Is this a sign that the
set needs re-aligning? Or is this normal?

: in 1-2 minutes flat and then the acid starting eating into the Nail

Ah yes, we used to use HNO3 to etch the copper buildup on the racks used for copper plating PC boards. Something nobody has mentioned (yet) is Hydrogen Peroxide/Sulfuric Acid etchant. Copper causes the peroxide to decompose, but for small amounts it works very well. Stabilizers are available from a couple of companys that supply chemistry to the printed circuit industry that can make it last. The 10% sulfuric, 10% (33%) hydrogen peroxide plus stabilizers work very well although the temperature needs to be somewhere around 100 degrees F or so (don't remember the exact recommended temperature.) It is an exothermic reaction so it will get hotter as the copper gets etched. If Ammonium Persulfate is used, some people have had some success keeping it going by plating the copper out of the solution. I believe Ammonium Persulfate will die at a couple of ounces per gallon of copper while the peroxide/sulphuric will start to redeposit copper somewhere around 7 ounces per gallon (depending on agitation, temperature, and concentration of the peroxide and acid.) The peroxide/sulfuric is regenerated by putting it in the refridgerator when the acid concentration is right, and the copper will come out of solution as copper sulfate. The Ferric Chloride dies somewhere around 4 ounces/gallon copper (as I recall.)

On the other side of things, some of the smaller pc shops will print and etch a pc board with no holes drilled, etc. for a nominal charge. When I still had the business, I would charge $25 for approximately 10" x 12" board for a tin-lead plated board etched and fused. It might be worth trying to get a relationship with a smaller pc board house to see if they will do the same thing. Oh, the turn-around time depended on how busy we were but was usually a day or so.

What frequencies are you talking about? You'll never decode 1 KHz in
1 millisecond! For FSK at up to 600 baud, I've used the XR-2211, once
made by Exar and now by whoever bought 'em out. It's designed for low
speed FSK demodulation.

>73,
> Jim Devenport WB5AOX

The capture area (in square wavelengths) of an antenna can be
determined from it's gain muliplied by the capture area of a dipole (I think
lambda^2 / 8). E.g for a 15dbd yagi on 2m that's a circle of 2m radius. So if
you stack 15dbd yagis on 2m at 4m intervals they will not interact and you
will get a gain of 2. The boom length for this yagi is 9m. You don't need
to separate the yagis by 9m. The edge of the capture area is not hard - ie
the gain doesn't suddenly drop as you move the yagis closer, and you don't
get exactly a gain of 2 at the separation calculated this way.

595. 1296 beacon suggestions ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-12 02:25:02 UTC
From: hduff@humnet.westonia.com
Message-ID: <7755-217275901@humnet.westonia.com>
Source record: 114246

I'm putting together a beacon for 1296 Mhz for the Toronto area
and would appreciate hearing from others who have done this.
Suggestions/ Tips ???

I've been thinking about the tradeoffs between minimizing line losses
and maintaining reasonable frequency stability. I considered mast
mounting the whole shooting match just below the antenna in a
weatherproof box but the temperature change here in Toronto between
winter and summer can be drastic and would probably have an adverse
affect on the operating frequency, especially after the oscillator
multiplication that gets you to 1296 Mhz.
On the other hand, mounting the whole thing indoors would require a run
of hardline about 50 or 60 feet or more so my 1 or 2 watts would be
whittled down to milliwatts. Short of adding a brick amplifier and
running 20 watts up the feedline and expecting a few watts out (which
would exceed my budget for the project), I'd like to be more creative to
accomplish the task.

Also looking for omnidirectional horizontally polarized antenna designs.

Many thanks ! Hugh Duff VA3TO/VE3OYH Toronto

a typical format and speed ? If that might be the case, I could easily
put a microcontroller between the radio and the PC...have each talk:
controller <--- ---> PC via normal RS232 and
controller <--- ---> radio using whatever it needs to see. A software
UART could be written into the controller and normal port pins do the
talking. Whatever you send from the PC to the controller could be
translated by the microcontroller into the appropriate datastream that
the radio wants to see. Of course, it would be a monotonous task to
document the flow of data from the logic analyzer for every funtion on
the radio. If someone is willing to work with me on this, I believe we
could master it.

BTW, I'd love to see that mod file to control the RF decks independantly if you have access to it ! I've been thinking that Kenwood should have offered a monoband head/chassis that would accept TM741/742 modules. That would have been a great way to market monoband FM rigs from 10 meters through to 23cm. I have some modules for my 741 kicking around... I'd like to put them to use, my 741 is already full.
If I knew what the RF decks need for data, I might be able to whip up a micro with an LCD display, rotary encoder and maybe a keypad to do this although, now that I think of it, all of the audio along with other functions are done at the head...maybe a little more trouble than meets the eye !? Certainly worth experimenting with anyway.

ALSO - be sur and check with Analog Devices. They have some new,
relatively cheap DDS chips. Harris also has some good DDS chips.

Also check with Phillips/Signetics regarding PLL's.

>Mini-Circuit Lab may have the VCO that you want, they are now advertising a series of VCO modules with low phase noise. They cover from something like 20MHz to about 900 MHz I believe (you have to check their ad). The prices are quite reasonable, they quoted me about $19 a piece with a minimum order of $50. Seems like a good deal to me. BTW, most of them claim a tunning range of 2:1 from about 1 to 15V.

Z-COM has some low-cost VCO's; also check with Phillips/Signetics, RF MicroDevices, and TriQuint for chips with oscillators built-in.

I may be able to help, but I need to know if you have a grid dip meter or any way to tune them. I
have built coaxial traps for dipole antenna's before. My way is a bit cut and try. If you haven't
done such a thing before, let me know and I will post a more detailed answer.

600. PC Card 50Mhz DDS Generator

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-12 18:31:07 UTC
From: erichter@editec.artinet.de
Message-ID: <7opPvAMMBh107h@editec.artinet.de>
Source record: 114251

For those of you out there who struggled until now to build a precise and reliable NF/IF/HF source, my latest developement may be of interest:

- short PC plug in card
- a 50 Mhz DDS Generator (based on AD7008)
- 32 Bit resolution (0,011641532Hz!!!!)
- Frequ. output 0,011Hz to 15Mhz (20Mhz is possible)
- output power >13dBm into 50 Ohm
- 4 channel 12 Bit A/D converter (with pre-amp�s)
- high purity signal

- Test SW available (incl. Pascal Source code, allowing for
fixed frequency setup and A/D test)

- Wobbulator SW allowing for any start/stopp frequency
build in adaptable error correction (non linearity of Demodulator heads)
Precise Raster Display to show all 4 channels in different colors
(resolution 1Hz!)
Power level readout (resolution 1dB)

This card is useful for (but not limitted to):

- NF-Testing (HiFi Bandwith, NF Filters)
- IF- Testing (smallest christal filters can be expanded over the total PC screen)
- HF Testing (Receiver Input Filters)
- VHF and UHF Testing with external mixers
- Reference Signal for High Resolution PLL circuits

The following complete support is available:

1) complete 76 page book describing all chips and circuit details
(circuit discription is currently in german, chips discription in english will be completely
available in english soon). Book comes wit Test SW.

2) professional Pc board with soldering stopp and Parts layout

3) Wobbulator SW

4) Complete Kits

5) Assembled and tested ready to plug in cards

>something like this.

FeCl3 (Ferric Chloride) has NOT etched the piece of stainless steel whip antenna I use for a "board pick-up" stick when I'm etching PC boards... at least not to this writing.

If the aquarium pump must be immersed IN the liquid in order for it to be pumped, I'd recommend AGAINST using the pump.

I've had very good success in using a small water pump. I found an AMXCO (American Excelsior Co.) #578 pump which has a plastic body and impeller. The shaft is made of steel, so I disassembled the plastic body and completely coated the metal shaft with epoxy to keep the etchant from attacking the metal. Then I reassembled the pump. This is a bottom-feed pump with a 1/4" to 5/16" output port right above the impeller housing. The pump is not all that high priced (less than $25) and it has more than adequate power to push a lot of etchant around in the tank.

NOTE: I had originally tried a "Little Giant" submersible water pump in this application. While the pump worked quite well, it was FILLED with a cooling oil and, once overheated, the sealing gasket let go and I had an etch tank full of etchant mixed with cooling oil... ruining my PC board and my etchant. The pump I now use is quite a bit lower priced and works just as well... maybe even better.

Consider keeping the reference oscillator in the shack and the rest
of the transmitter up at the antenna. That way you can use cheap
cable to carry the reference up there since it will be operating
at a relatively low frequency.

>Also looking for omnidirectional horizontally polarized antenna designs.

Consider a cylindrical slot array.

Hugh:

Why not use an oven on the XTAL? That's what we do and our frequency
sources are stable to within +/- 5 ppm from -25C to +70C. That should
be good enough for your application. The ovens are manufactured by
ISOTEMP and should be about $20. If you're clever anough, you can make your
own oven that should be close in performance to the commercial ones.

Also, if the beacon is going to be CW, I wrote an article in the February
issue (1994) of QEX that may suit your needs.

I think, that it is OK to have all on the mast top. A good practice
is to thermally insulate the VCO (+ any other low power components)
or even provide a small amount of temperature controlled heating.
Of cause the unit should be protected from direct sun light.

Temperature controlled heating could be done with a temperature sensor,
an op amp and a power transistor as heating element.

Are you asking if it is okay to blast away on 2 meters with pulse modulation?
Or are you just thinking out loud? You have a license that authorizes you
to transmit on the 2 meter amateur band. Presumedly you are familiar with
the contents of part 97. Then you have your answer. Simple, isn't?

Jim

Hi Nick. The oven idea sounds like a possibility ! I'll look into it.
Do you have a CDN source for the ISOTEMP ovens (Qty 1) ?

Yes, the beacon will transmit CW. I think I'll use a single chip PIC to
do the keying. I also have a 6 meter beacon running here in Toronto
and for that one I used an 8031 microcontroller..sort of overkill but I
had access to bare boards and the processor, latch and EPROM cost me
less than $10 and it saved me the trouble of handwiring something like
a 555/counter/EPROM keyer. (See my 6m beacon article in November 94
TCA).
What is your QEX article about ?

617. Ramsey FM-4 dirty output

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-14 07:41:51 UTC
From: alf@kaiwan.com
Message-ID: <8Y5GlClg1e8A068yn@kaiwan.com>
Source record: 114268

Greeting to all!

I have built a Ramsey FM-4 4 transistors FM wireless mic and am having some problems. I plan to use this as a no ID required very short distance repeater. I am posting this in hope of some kind souls out there can offer some pointers.

I have build as per instructions, keeping all lead short. Every things is as best as I can manage. Transistor polarity has been checked. It powered up fine without smoke nor smell. Tuning the oscillator tuning coil I can actually receive the audio on an FM radio across several rooms at perhaps 40 feet.

All seems fine except I can do so only in a very narrow band of frequency of perhaps 500 kHz. When using a 500 MHz scope with short lead to look at the output, the problem becomes obvious. In the working frequency range the output waveform looks like a half way decent sine wave, with as a wild guess of perhaps 10% distortion. In other frequencies the output has severe distortions. At its worsest it has perhaps 50% 2nd harmonic distortions. And these are by visual guesstimation. As a result, it cause serious interference to many FM stations and without any usable audio output.

I wonder is there anyone on the net has experience with such gadget? I would appreciate any suggestion or comment, such as adding a filter. Thanks in advance.

73,

Hello OMs !

My father OE5LCO read in the magazine QST (January '95) the article
"Quick and Easy CW with your PC" written by WB8DQT.

He would like start this project, but there is also software necessary, which
WB8DQT has written.

The only problem is to get this software.

It seems to be only available at following entries:

- ARRL BBS 203-66-0578

- CompuServe HamNet forum library 7.

and it is called "morse.zip".

This zipfile contains "morse.exe, cw.dat, log.dat, cw.hlp" and
"morse.bas" (a QuickBasic source code).

Neither my father OE5LCO nor I are able to get access to one of those entries.

So it will be very kind , if someone helps us to solve this problem.

Tnx in advance
Hans Czylok

How good are you at writing machine language state machine code?
If the answer is "not so hot", then you'd better stick with the
TNC2 design and use B or H Z80 and Z80 SIO parts. You can get the
proper ROM image from TAPR.

I need some help in designing a 1927s vintage CW transmitter.
I want to use a one tube crystal oscillator driving a pair of
P-P 10s with balanced input and output. My questions are:

- how much power will I need from the oscillator stage to drive
the "final" amplifier? I want to start on 80 meters. The
power output needed is 8 or 10 watts. A #10 tube has a mu
of about 8 and a Gm of about 1500.

- how do I design the transformer coupling between the oscillator
(single-ended) and the balanced input to the P-P stage?

- what is the best (and authentic!) way to key the transmitter?
Is cathode keying OK or would keying the crystal oscillator
be better? When I eventually get a license, this thing has to
be legal and sound good on the air!

I am not an RF designer, but am willing to learn. Thanks for any
advice.

Maybe the crystal set isn't such a bad idea. If talking about how radio flies through the air to make the voice happen seems too abstract for him, maybe you can make it more concrete with a telegraph set: get a telegraph key, a battery, and a light bulb. Show him that you can make the light go on and off as long as the wire is intact.

Now, replace the wire with empty space, build a little milliwatt transmitter, and a crystal receiver driving a switching transistor, and show him that you can make the light go on and off WITHOUT a wire, too.

A substantially more sophisticated radio demonstration that I saw recently (you might want to wait until he's 6 :-): at the Boxborough ARRL convention, "The Wireman" did a demonstration with a 910MHz transmitter hooked up to a simple dipole on a stick, with a crystal-set-and-light-bulb somewhat as described above also connected to a dipole on a stick. Using these two antennas, he was able to visually demonstrate polarization and the inverse square law. Next, he mounted the receiver's dipole on a pegboard, and put another wire on a stick behind the dipole; the wire was just longer. Voila! Instant 2-element beam, and sure enough, waving the transmitting antenna around changed how bright the light bulb was, just like those pictures in the ARRL Antenna Book say it should. And that is the whole point -- it's one thing to read a description of antenna patterns and see a 2D picture in a book, it's quite another thing to build your own antenna range (which is physically practical at 910MHz) and *see* it work. The Wireman suggested that clubs might want to build sets like this for staging demonstrations.

Nice. The reason why is that 1200 baud tele. modems are bell 212, a full duplex system with four tones used. Packet is bell 202 a simplex system with only two tones (and different ones at that) used. TI's 3105 is a good choice for generating and receiving the tones. One would have to do all the upper layers too. But it is true one could reuse the case and power supply.

Looks like you need about 0.5 watt of oscillator drive.

> - how do I design the transformer coupling between the oscillator
> (single-ended) and the balanced input to the P-P stage?

That's pretty easy. The primary will be in series between the
oscillator plate and B+. You can tune it, or use it untuned
depending on the oscillator circuit you use. The secondary
should be center tapped with bias for the PA tubes injected
there, and the winding ends going to each tube.

> - what is the best (and authentic!) way to key the transmitter?
> Is cathode keying OK or would keying the crystal oscillator
> be better? When I eventually get a license, this thing has to
> be legal and sound good on the air!

Cathode keying would be authentic, but with a 0.5 watt oscillator,
you'll have a strong backwave. If you key the oscillator, you'll
get chirp. The best way is to use differential keying. You arrange
the circuit so that the oscillator is keyed on before the PA so
that the chirp will be over before transmitting, and the PA is
keyed off before the oscillator. There were complicated delay
circuits used years ago, but a pair of relays, one keying the
other, will do the job.

633. Dielectric Grease, NOT!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-15 16:36:04 UTC
From: Waltk@PICA.ARMY.MIL
Message-ID: <9502151136.aa04690@COR5.PICA.ARMY.MIL>
Source record: 114282

Dielectric Grease, NOT!

Howdy. This should put an end to all the comments on my earlier posting on how to bond dissimilar metals. Someone (can't remember who or they'd be getting a personal copy of this memo) told me something I've never heard of - dielectric grease. I keep an open mind and love to learn new things, like the rest of you. So, I posed a question to the net. Well... the response was overwhelming.

I have used No-Alox(tm) and Penetrox(tm) for years on my yagis, and even in the service entrance in the house I built 10 years ago. Most wiring to new homes uses large aluminum cable, Cu is just too prohibitive in price for the application.

So, I want to lay to rest this business of dielectric grease, it doesn't exist and was a fig-newton of someone else's imagination.

If binding dissimilar metals, a conductive grease is what is prescribed. 73 de Walt - K2WK

PS: I would recommend to any novice getting on the air, that they also subscribe to the net. I've been in this hobby almost 30 years and am still learning from my esteemed (sometimes steamed) colleagues.

I would imagine that un-sticking the cores and not breaking them can be
an ellusive task. A solvent that I have used around plastics without harm
is kerosene. I will dissolve gumes, resins, waxes etc. Kerosene appears
to be an oily like solvent which is not harmfull to plastics. If you
are going to use a soldering iron as was suggested, I would first try it
on an isolated slug tuned coil from some old junked radio gear to get an idera
of heat damage coilf form distortion etc. Good luck

>The suggestion about kite antennas is a good one. They work really well
>on a mountaintop because you can be certain of enough breeze
>to keep them up. Stretch a counterpoise along the ground and
>you will do quite well.

I have used kite antennas or a few years also. The kite is a parfoil,
4 section. I have used it at the shore in Florida Where there is always
either a shore breeze or an ocean breeze. I have used wire from T.V.
yolks because it is cheap ($0.00) and light enough not to drag the kite
down. I have used VEEERY long wires which will behave like a many element
beem with a narrow lobe. When I have a shore breeze I am " beaming " to
Europe. My HW8 with 1 or 2 watts and a home brew tuner does wounders.
The parafoil kite has no firm members and so it can be balled-up or rolled-up
astuffed into a back pack. I am currently working on solar power for the Fla.
beach.

>>73's Joop PA3ABA
I'd recommend using an existing microprocessor, such as the Commodore 64 or an IBM PC/clone, since very powerful shareware exists already for doing just what you want, and require only a rather elementary 1 or 2-IC modem to interface your computer to your radio to form a full function TNC that, for packet only, works better than most commercial TNC's IMHO. The software is called Digicom for the C-64 and Baycom for the IBM PC. If you have trouble finding sources for the software (many BBS's) let me know... you can get some of the earlier versions off Hamnet on Compuserve, also by landline from the 73 BBS... dunno how available they are in your part of the world, I could put them in our local anonymous FTP site if you like. I can also provide schematics for the simple modem needed.

I'd suggest putting the frequency reference in the shack. Buffer it
adequately and send this signal up the coax to the rest of the system
mounted near the antenna.
Assuming you're starting from a crystal oscillator in the 100MHz
range, the line loss would be fairly low, and low level amplification
would be cheap in any case.

Good luck,

Alf NU8I/G4ABB

>
Well I have to disagree with this. Dieelectric greese most certianly does exist. Its just not what you want for joing two alum tubes together. Dielectric greese is an insulator and is widely used by tvro technecians to make F fittings water proof. Some disagree with its use and I have not decided on its merits. It is also used in some automoble distributers. Trouble is its purpose is to insulate and in the alum joining discussion a low resistance connection was desired.

Depending on the qualities you need, heavy-duty braided fishing line
from a tackle shop (probably not available at your generic sporting goods
store) might do the job at considerably lower cost. Dial cord and braided
fishing line are similar in appearance (except for color) and exhibit almost
no stretch under tension.

Garry-

Use of a non-conductive grease for waterproofing connections, be it silicone, automotive or petroleum jelly, has been common for many years.

It seems that the pressure of spring-loaded contacts squeezes out the grease, allowing the metal contacts to touch. The grease MUST be non-conductive, in order to prevent shorting between non-touching conductors. (In the case of dis-similar metals, I worry that the reaction might contaminate the grease, making it conductive.)

Use of grease is messy for home applications. It would be of little value where corrosion was normally not a problem. However, it works well in a damp environment, such as in an automotive signal lamp with a cracked lens!

Hi

I am looking for information and schematics on modifying
an ICOM 4AT that is in the upper UHF segment of the Band
(440.0 up) to the lower segment (436.0 ? - 439.99) There
were a few different chasis built for these bands,
and I would like to change the parts required and retune it
to cover 436 - 439.

I will pay for shipment and reasonable copy expenses.

If someone performes this types of modifications
for a living, I would also appreciate their
info, as I might consider paying someone to do this.

Thanks

Maurice

What DAC are you using with the Harris NCO? I contacted Harris and they
recommended a Sony device. I ordered a couple before I got the documentation,
found that they needed ECL converters, and promptly lost interest 8-(.

You could do what the old PC cassette-tape interfaces did: at the transmitter you send a single 1200 Hz pulse for a '1' and a 2400 Hz pulse for a '0'. At the receiver you square up the received signal with a comparator (or just use a TTL input as the comparator) and measure the pulse width.

I've been fiddling with a power amplifier for a while, starting with the Motorola 20 watt design that appears in schematic form only in the W1FB QRP NOTEBOOK. (Push-pull MRF476's drive a push-pull pair of MRF475's)

Well, I had a wonderful power oscillator at about 5 watts, and thus began numerous experiments with different ferrite baluns I had on hand, biasing schemes, running only the first pair for a while, etc.

I tried to run the MRF476's separately near their ratings (6 watts total), and got thermal runaway over 1 watt -- the 82 ohm series resistor to the bias diode was way too low. In experimenting with bias, klutzy testing with my scope probes, solder bridges, etc., I have gone through about 3 pairs of '476's! (ouch!)

Along the way, I got the locally available NTE replacements (near equivalents, maybe) for the 475's -- the NTE236. (Their book is WAY off in its suggestion of a sub for the MRF475!) It was interesting that, on a DC check with the diode test function of my DVM, they have a .7 volt diode barrier voltage between emitter (plus) and collector (minus). Does this imply a built-in protection diode? They work fine, putting out 6 watts (they're rated at 12 watts out apiece, so I have some reserve -- I don't want to blow more expensive transistors!) The package calls it an "NPN-T" transistor -- does that give a hint?

Was also thinking of putting in some MRF477's in the second stage (pinout different, but I can adjust my board). Any reason this should not work in the Motorola circuit, with care in biasing and drive? I will probably run them at 40 watts max out for the pair (rated 40 watts each) -- again, I'm skittish about popping out more transistors. I have an Amidon BLN-43-7051 core, which I hope is big enough!

Source record: 114303

... I also build a DDS board which is a plug in card for a PC. But it is based on the Analog Devices Chip AD7008.

Here is some more info:

For those of you out there who struggled until now to build a precise and reliable NF/IF/HF source, my latest developement may be of interest:

- short PC plug in card
- a 50 Mhz DDS Generator (based on AD7008)
- 32 Bit resolution (0,011641532Hz!!!!)
- Frequ. output 0,011Hz to 15Mhz (20Mhz is possible)
- output power >13dBm into 50 Ohm
- 4 channel 12 Bit A/D converter (with pre-amp�s)
- high purity signal

- Test SW available (incl. Pascal Source code, allowing for fixed frequency setup and A/D test)

- Wobbulator SW allowing for any start/stopp frequency
build in adaptable error correction (non linearity of Demodulator heads)
Precise Raster Display to show all 4 channels in different colors
(resolution 1Hz!)
Power level readout (resolution 1dB)

This card is useful for (but not limitted to):

- NF-Testing (HiFi Bandwith, NF Filters)
- IF- Testing (smallest christal filters can be expanded over the total PC screen)
- HF Testing (Receiver Input Filters)
- VHF and UHF Testing with external mixers
- Reference Signal for High Resolution PLL circuits

The following complete support is available:

1) complete 76 page book describing all chips and circuit details
(circuit discription is currently in german, chips discription in english will be completely
available in english soon). Book comes wit Test SW.

2) professional Pc board with soldering stopp and Parts layout

3) Wobbulator SW

4) Complete Kits

5) Assembled and tested ready to plug in cards

655. Biasing RF power transistors

Newsgroup: rec.radio.amateur.homebrew

From: jdc3538@ultb.isc.rit.edu
Message-ID: <1995Feb20.033309.25392@ultb.isc.rit.edu>
Source record: 114304

When biasing an RF power transistor for linear operation, is the end result a fixed base voltage or fixed current? The Motorola app note on biasing for linear operation (AR511) mentions a .63-.67 volt typical value. But construction projects say to adjust bias to a given current draw, say 100 ma.

Which view of it is right? And where does temperature compensation come in?

This very interesting method has been proposed a long time ago.
Unfortunatly I could never see it working well. The islands formed
at some places very early and interuppted the electrical continuity.
They could only be removed with usual etchant, nearly resulting in an
usual eching process.

Is it possible to avoid these drawbacks today ? What is the used solution ?

: > current draw, say 100 ma.
: > Which view of it is right?
: >
: When you are biasing for linear opperation, the answer is almost fixed
: voltage. What you actually need to do is supply enough base bias current
: over the whole of the drive cycle. This may be two or five mA for the
: standing bias (giving the typical 100mA collector current) or up to 1A at
: the peak of the drive cycle(up to 15A collector current). As you may be
: able to guess from typical ib vs. Vb curves this is not stricly constant
: voltage but pretty close. Adjust your bias for 100mA or whatever the
: transistor manufacturer's recommended value is, but also check that your
: bias supply will work under full drive conditions.

To amplify what John says, it's very important to design the bias
supply to be able to deliver the maximum base current required at
peak RF drive power. Many commercial PAs don't do this, and the
transistor slides towards Class C on speech peaks. The rest of us
can hear the results all across the band!

The conventional bias circuit with a diode and a resistor is basically
a shunt regulator, and needs to be shunting many times more current
to ground than it's asked to deliver to the base. In other words, if
Ic = 15A and Ib = 1A, the bias circuit should be shunting several amps
to ground at all times. As I said, most commercial circuits fail
miserably to do this.

A much better answer is an electronic bias regulator which adjusts
itself according to the current demand. In that case the standing
(shunt) current in the base bias circuit need be only a little higher
than Ib_max. Motorola, Philips and other appplication notes give
suitable circuits.

: > And where does temperature compensation
: > come in?

:
: As the temperature of the base emitter junction in a transistor rises, the
: current drawn from a fixed voltage bias supply increases and consequently
: the collector current goes up.

Specifically, as the PA transistor junction heats up, its Vbe voltage drop decreases and the constant-voltage bias supply pushes more current into it. This in turn increases Ic and tends towards thermal runaway.

: Therefore to prevent the RF transistors
: going into thermal runaway the base bias supply requires temperature
: compensation to reduce the bias voltage when the RF transistor gets hot.

Usually this is a diode which is mounted on the heatsink close to the PA device, arranged so that the bias voltage drops when this diode's Vbe decreases. Better than a wire-ended diode is the diode made from a TO220 PNP transistor with base and collector connected together, and the collector tab bolted down to the heatsink. (Draping a wire-ended diode across the top of the PA transistor is really pretty pathetic.)

The problem is that the diode junction can never accurately track the temperature of the PA transistor junction, except over timescales of several minutes. Thermal runaway, on the other hand, can be all over within a few tens of seconds. Unless the PA is one of those rare and fancy devices with an on-chip temperature compensating diode, the only solution is a larger heatsink - yet another area in which many commercial PAs fall short.

Perhaps the best solution of all is to use RF power MOSFETs, which don't have the same thermal runaway habit as bipolars (they have other methods of suicide instead).

664. Fix for loose IF slugs?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-21 06:02:12 UTC
From: Wayne Hall <74361.2114@CompuServe.COM>

I have a vacuum tube transceiver whose former owner must have done too many alignments because the rf and if transformer slugs have become quite loose and the rig won't keep an alignment for long. I thought about the old trick of using wax to hold the slugs but I suspect the temperature in the rig may be too high for wax to hold. Has anyone tackled such a problem before?

Thanks,
Wayne Hall

Wow, you guys are really creating old-time crystal radios? My Grandfather had a radio-making business during the depression. When I was about 10 years old (1964) my dad and I were given a few boxes of Grandpas old radio parts. My dad and I then made our own crystal radio, using the technique of poking a cat's whisker onto different parts of the crystal. We used only hand made stuff. It was wild and worked very well. Before he died, Grandpa gave me all his old electricity encyclopedia that he had bought in 1914 and it tells how to make everything that was known then, including a crystal radio. Up until Grandpa died (1993), he used a crystal radio he had build a few years before, as well as a modern-day CB radio. He even used to make his own batteries and tubes from scratch!

You might consider purchasing the QSK-5PC module from Ameritron.
Single circuit board - not overly pricey... and it works very very
well.

Hi All
I have been looking on the net for a site with transistor and IC
equivalents and specifications. I've only been on line for a short while
so perhaps I'm not doing the searches right.

My present interests are QRP Tranceivers which can be built without
special bits ie ferrite/iron powder cores, mixer IC's etc. These are
not available in my local Tandy or Dick Smith store.

Best regards and 73 from Steve VK2SPT

Greetings Steve.

Tandy and Dick Smith, as you know, have a limited range of radio type devices and IC's, which can rather "cramp your style" if you want to build circuits from QST etc. Trying to substitute so-called "equivalents" can be rather frustrating too. A good project writer will always try to use and specify devices which are available (at time of preparation), so why not simply take advantage of the information given? Buy your components mail order- it's easy and fun (a bit like receiving a little present in the mail- only you pay for it).

Like to build a neat little 80 M SSB/CW transceiver using easy to get parts? See "Amateur Radio" Oct 1993 (40 M version in preparation).

73, Drew, VK3XU. Telecom Australia Research Laboratories .
you don't have a Most good project pr, because they never are the equive.

I believe the Motorola MC3362 (or newer version) will decode 1200 Baud FSK. It is a Dual Conversion rx, inexpensive and uses inexpensive parts. Uses common 10.7 IF filter then 455 Khz filter both in DigiKey catalog. Contact me if you need help finding parts.

However, 1200 bps packet uses AFSK, not FSK. Both QST and 73 Magazine have projects to make a packet modem, which then uses a software TNC (SoftKISS 1.8 on a Macintosh -- references upon request). If you want to talk to most of the folks doing packet these days (in this area at least), that's probably the best homebrew way of getting started. It's one IC and for the Mac, steals its power from their differential equivalent of RS232. (Add a timer IC if you want to run unattended, in case the CPU crashes with PTT asserted.)

I believe QST also has a receiver project using the MC3362, including PC artwork (get the corrected version, reference upon request), but that copy had been filched from my local library, so i haven't chased down that reference myself. I haven't had a chance to look, but i think Ramsey has a 2 meter receiver kit which might be a convenient way of getting the parts to get started with even if you choose not to use his design.

The first hetrodyne oscillator is left up to you as a project though.

If you do your own VCO, Motorola claims you can work the 440 band. The MC3363 is a slightly smarter chip, but you'll have to find a adapter to go from surface-mount to DIP. Needless to say, use a good ground-plane and be careful about layout.

Two questions:

Has anyone tried using the Motorola stuff at or above 9600 baud?

Anyone in the Bay Area interested in elmering me on this stuff? While i've hacked TTL using early CAD software, RF is new to me.

Motorola also makes transmitter chips which cover the 6M band, and i wonder if that might be an interesting place to experiment. In my area, the local band plan only lists four packet channels, but two are currently listed as experimental, as opposed to sixteen in 2M, all of which are committed. The 220 band has the same problem, but isn't subject to a 20 KHz bandwidth restriction.

The first hetrodyne oscillator is left up to you as a project though.

You can use the IC's VCO at 2M and below, and "the MC3363 [apparently the same VCO] can be used with the MC14515x series of CMOS PPL synthesizers

and the MC120xx series of ECL prescalers in VHF synthesized applications to 200 MHz".[[Motorola Telecommunications Device Data, p. 2-52]] Perhaps a simple 10-turn trim-pot might suffice for bench testing, at least to determine that receiving digital is worth pursuing via this route.

Good luck (and let me know what happens).

-- KD6PAG (a networking old-timer)

675. Building radio into computer - need advice

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-23 19:20:38 UTC
From: dbrennen@ix.netcom.com
Message-ID: <3iin66$a86@ixnews1.ix.netcom.com>
Source record: 114174
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.scanner,rec.radio.amateur.shortwave

I'm building an interface card for an IBM 486 as a school project. The card would be a radio frequency tuner that would be controlled by a window on the display. I want to include the standard FM band (I have a commercially made card that does this already), but would like it to tune 1 or 2 more bands that would be of interest to an average PC user (like weather or aircraft). What I need are suggestions on: which frequency bands to include, which electronically tunable chips to select, and any other ideas on ways to make this project work. Thanks for any help. Sean Manning.

676. Re: Air core coil in VFO?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-24 02:34:05 UTC
From: royle@tekgp4.cse.tek.com
Message-ID: <3ijgit$mvn@tekadm1.cse.tek.com>
Source record: 114176

randolph@est.enet.dec.com (Tom Randolph):

>Anyone ever experiment with air-core coils in the VFO tank?

>I'm in the planning stage of a 40m rcvr. I want to try to get rid of some of
>the drift problems associated with toroids in the VFO at this time.

>. . .

I did quite a few experiments with inductors some years ago, particularly looking for ones with low drift as VFO inductors. Here are some of the things I found:

1. Make sure you know what the sources of drift are. It's quite common to see a design which compensates lousy capacitors with a lousy inductor. This approach tends to be poorly repeatable. I've tried to minimize drift from all sources, and came up with a simple oscillator I used in my little "Optimized" QRP rig. (See the '94 Handbook or a couple of issues before that. Note that there's an error in the buffer circuit in the '92 Handbook.) Good-quality NPO ceramic capacitors were found to have the lowest drift.

2. In general, air core inductors aren't the best. This is because unless they're quite large, they tend to have lower Q than a properly-designed toroid. Also, solenoidal inductors produce a large field. Besides the problems of crosstalk, coupling into shields, ground planes, and other objects lowers the Q, sometimes severely. Lower Q increases heating and therefore drift.

3. The best material I found for an inductor was type 6 powdered iron. Type 7 (not available when I did my experiments) has a slightly lower specified temperature coefficient, but has lower permeability. This might result in a lower-Q inductor, which could offset or negate the gain due to the lower tempco. Wes Hayward, W7ZOI had an article in QST a year or two ago outlining simple ways to do good, repeatable measurements of oscillator drift.

4. I couldn't find a ferrite which came anywhere near the powdered iron in low-drift characteristics.

5. The design I ended up with is quite repeatable and exhibits about 200 Hz warmup drift at 7 MHz. This can be compensated if desired with a small amount of polystyrene capacitance as part of the tank C.

6. There are very few materials you can coat a coil with without lowering the Q very noticeably. Among the ones which will lower the Q substantially are epoxy, hot-melt glue, and acetic-acid-curing RTV. It's best to leave the coil uncoated.

Hope this helps.

73,

> beastie for QRP stuff, but none of my references have the device listed.
>
> Would appreciate the data on it. Either reply here or email is fine.

Ptot (max) 1 W
Vds (max) 60 V
Vdg (max) 60 V
Vgs (max) 5 V
Gate threshold voltage 0.3 to 2.5 V
Igss (max) 10 uA
Forward transconductance 200 mS
Id (max) 0.5 A
Idss (max) 10 uA
Max I/P cap. 48 pF

I don't have a data sheet, but found this in a Maplin catalogue.
Unlike the VN66AF, which is given as 600 MHz, the max. freq. isn't given,
but it should be quite suitable for HF, like the VN66, which is often
used for QRP, I think.

Hello

Sorry to inform you but you CAN solder copper to aluminum!!

I have done it many times using a heavy-duty soldering iron, common solder and some hi-temp oil to provide a barrier to atmospheric gasses.

I have tried every special solder for AL I could find. They all work to some degree. They all have two failings. They are brittle and they are "short" they go very quickly from solid to liquid. You can not make a "bead" like you can with brass and to a lesser extent solder.

Most have less resistance to crosion than AL or solder. I also suspect that there could be electroletic crosion(sp) problems.

Most are stronger than AL.

>dave
>
Heathkit stuff usually comes with some documentation, and most users
tend to hang on to it. If you can find out the frequencies of the
original CB crystals, you might be able to figure out what
crystals you need to convert from CB (26.9 to about 27.4 Mhz) to
10 meters (28.0 to ... 29.something). It may have used 3rd
overtone crystals, about 9 Mhz, and it may have used heterodyning,
so sums and differences might have been involved in getting into
the CB range. Phil Emerson, AA8JO.

684. "W7ZOI" mod to R2 preamp?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-02-25 04:19:03 UTC
From: rohrwerk@orac.holonet.net
Message-ID: <3imb3n$4j1@colossus.holonet.net>
Source record: 114184

December 1994 QRPp has an article by John Liebenrood, K7RO, on his transceivers using the Rick Campbell R1/R2 receivers and T2 exciter.

I am scratching my head about his suggested modification to the preamp after the diode ring mixers that claims to "reduce the noise figure from 20 dB to 12 dB".

It's even attributed to Wes Hayward! Shall we genuflect? ;) Well, this skeptic has some doubts before accepting this on faith.

The original circuit is just like W7EL's "Optimized QRP Transceiver" -- a common-base 50 ohm preamp, an active decoupler transistor, and an emitter follower.

The modification suggested in John's article basically makes the second stage a common emitter amp, thus increasing the gain. But does this reduce the "noise figure", ladies and gentlemen? Something sounds fishy, or maybe some terms were used loosely.

Rick said most of that high noise figure (the amount greater than the 12 dB or so attributed to the mixer loss and preamp noise) was due to diode flicker noise below a 10 kHz IF. If this were so, additional gain after the mixer and first preamp stage would not change this!

Is it possible that under some circumstances this extra gain would override the noise of succeeding stages? If this were so, it would seem risky because of the overload margin of the stages following (in the R2, at least, where the preamps are followed by opamp audio phasing networks).

Comments?

Absolutely, the oil's the trick. Scratch the aluminum bright under
the oil to get rid of the oxide coating, tin the aluminum with a
hot iron and regular solder *through the oil*, clean off the oil,
and then solder as normal. This is a great way to make soldered
connections to aluminum chassis.

I believe you'll find it's mostly heavy, 'Murriken ahrn from the '50s
and '60s with names like Johnson, Heath, Globe on their front panels.
However converted CB sets work great when there is a band opening.

29.0 seems to be the general AM calling frequency. There is AM activity
from 29.0 to 29.2

Cross-posted to: sci.electronics,rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Hi,

I'm after a circuit design for a 5KHz receiver. It needs to be
a compact and low-power. It's detecting a 5KHz pulse that's
being generated from a very weak transmitting source.

Does anybody have such a circuit or is able to point me in the
right direction. My digital knowledge is good, my analog and rf
not so good.

Thanks in advance.

Peter.

>Roy Lewallen, W7EL

Thanks, Roy, and everyone else who responded. This is exactly the kind of info I was looking for.

I understand the drawbacks of solenoidal inductors, and am planning the VFO box/board layout to account for them (yup, it'll be pretty big and mostly empty). We have an HP impedance analyzer here at work that I'm planning to use to check the Q of the final coil. If I can't get decent results, I might go back to a #6 material toroid.

Source record: 114196

Anyone on here using the digital voice recorder chip that Radio Shack has been selling? I forget the number. It will record/playback up to 20 seconds of audio. Normally sells for about $20 but last week my local RS had them on sale for $12... so I bought one.

I hooked it up over the weekend. Neat little chip. Non-volatile too. You can also cascade the chips for longer recording times.

It has a 6.4 KHz sample rate yet I would judge the overall audio quality as being at least good telephone quality or better. With an external amp/speaker it sounded pretty decent... even with music.

Anyone else playing with this chip? Not sure how much longer they are on sale.

Source record: 114200

I have one of the kits (unassembled) and 2 of my friends have them
assembled but we are a little slow in getting them tuned up.
The quality is very high. The cases are good too.
Ten Tec says the reason they put them on 20 meters was the proliferation
of compatible QRP kits available for 20 m. (I guess they are right
about that, but what about the Radio Shack 10 meter rigs which would
make great drivers for them).

Also, the docs are fantastic. There is a LOT of work that has gone into
the documentation. Very easy to use. Its a spiral bound book, lays
flat. Impressive.

You might like to check out the article "Communicating Underground" (or some such) in the December 1994 issue of Electronics World & Wireless World. The article contains a transmitter and receiver operating at 874 Hz (not kHz, nor MHz, just plain Hz!) for cave work... It might help you along the road.

Henry Radio carries a line of Japanese relays similar to the Dow-Ley
style - probably available with auxilliary contacts.

Also I.C.E. has a line of antenna switching relays, but I don't think
they have aux contacts.

I use an old Dow-Key DK-60 with a 110vac coil and have had no
trouble with it at typical (120v) line voltage.

Try cleaning the coil (and the roller) with a spare amount of contact
cleaner on a lintless cloth. Leave nothing on the roller or coil when
you are done. Check the tension of the roller against the coil. Clean
the rod the roller spins on....and the contacts against the coil end.
I could go on.....I think you get the idea.

Comet cleanser makes a good mild abrasive for grinding crystals.
Use a sheet of glass as a working surface, and go slowly, rinsing
and testing often to avoid overshooting the desired frequency.

Any high temp oil will work. Transformer oil is great, but you can get
by with ordinary motor oil, though it will smoke a bit.

AN>Just a quick question. Is it possible to change the frequency of
>crystal by sanding/filing them etc? I have some crystals for a low
>frequency and would like to make them oscillate at a higher
>frequency... can I do this?

Yep, it's possible... not necessarily EASY, but possible.

We used to 'move' crystals up 'n down the band, by hundreds of kHz, but
I never had much luck in moving them over widely divergent frequencies.

To LOWER a crystal's frequency, you can often do so by VERY LIGHTLY
rubbing a pencil lead (or piece of solder) across the face of the
crystal... to make it heavier, and thus slower to oscillate. It's
best to place your "mark" on that portion of the xtal where the pressure
plates DO NOT touch!

To INCREASE a crystal's frequency, you can grind it a bit thinner by
making a THIN paste of toothpaste (or abrasive cleanser) and water,
putting a little puddle on a FLAT glass plate and then placing the xtal
in the middle of the puddle and LIGHTLY sliding it in a figure-eight
pattern a few times. WASH it off, dry it, install it and see what it
took you.

It's all a cut 'n try process... as much magic as anything. Be prepared
for failure(s). I have had a lot... It's fun, but takes time,
patience, and the resolve to start over... and over.. and over...

Pete, I use this chip in the fox transmitter controller. Article was in
73 magazine. I have built three of them. You are correct, it is a very
neat chip. The local RS had them on sale also and I bought one. Decided
to go back and get some more and guess what - they were $20.

Oh well. It was worth the $20 to have a voice id for fox transmitter.
BTW I have also recorded CW as an IDer.

Last point, the circuit in 73 magazine has a problem and does not work as
published. The chip would not record with the connections shown in diagram.

Have fun with it.

For an even cheaper solution, look for my article in the April issue of QST. I have used the board from a Hallmark card ($7.95) to make a DVK, and you can easily convert it to a fox/beacon with a 555 timer. This is the same unit used in the little foxes described in the latest 73.

Hello, Pete. I got one last summer to play with. My club used it as
a CQ generator in the idle times when we were running a special event
station. It worked fine. I haven't had it inline lately, though.

I've been playing with automated CQing with my computer and
soundblaster card... As long as it's there, I might as well use it.

722. HELP !! Gunnplexer video link...

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-01 01:32:16 UTC
From: mikey@gnv.ifas.ufl.edu
Message-ID: <1995Feb28.203216.6248@tower>
Source record: 114127

I am looking for help with a pesky problem using 10 GHz Gunnplexers for a wide-band video microwave link. I am having difficulty getting LOW (yes, that's LOW frequency) response. The high freq components look great, color looks good, and a multiburst test signal looks good out to over 10 MHz of video response. The problem is that the video sync tips recovered by the TVRO receiver at the receive end of the link are severely rounded off and there is severe tilt in the low frequency components of the vertical interval. Please reply to my personal e-mail address: Mikey@gnv.ifas.ufl.edu

The idea is to use a Gunnplexer at both link ends, and a standard TVRO receiver at the receive end of the link. Instead of the 18 - 26 MHz wide-band FM video signal coming from the usual satellite system LNB and downconverted to a 950 - 1450 MHz IF, the receive-side IF is derived directly from the mixer port on the receive Gunnplexer. With the two Gunnplexer freqs offset by whatever the desired IF is (in my case 10.250 GHz on one end, and 10.320 GHz on the other results in a 70 MHz IF at the mixer output port).

This 70 MHz FM wide-band IF can then be amplified and fed directly into the IF input of a standard satellite TVRO receiver, and the video recovered in the normal way by the PLL demod. The FM video bandwidth appears to be about right (20 MHz or so) when looking at the receive end g-plexer IF output with a spectrum analyzer.

The IF level at the g-plexer mixer output (after amplification) with a 70 MHz broadband amp is just the same as what would normally be seen when the receiver is looking at a satellite via the TVRO dish and the BDC.

The linearity of g-plexers is claimed to be excellent out to over 100 MHz or so, as long as the varactor voltage swing (0-20 VDC max) is not too close to either end of the varactor voltage limits.

The varactor is driven (FM modulated) by a video buffer amp to about 6 volts P/P. The modulating video from the buffer amp is decoupled by a 470 uF wet-slug tantalum, and DC bias is derived via a 10-turn pot to establish the center operating frequency of the Gunnplexer. The modulating voltage swings from 8 - 15 VDC at the varactor input.

Basically, we just turned up the video drive voltage until we had about the right (18 - 20 MHz) deviation. Because the video buffer/driver amp is very low impedance (a few ohms) we can look directly on the varactor input with a scope probe and see that the video looks perfect there.

A multiburst test signal viewed at the varactor input also looks excellent, with SUPER high freq response out to the highest multiburst band (10 MHz), and the sync and low freq components of the vertical interval also look excellent.

HERE'S THE PROBLEM...: the recovered video from the satellite receiver at the far end of the link has VERY BAD LOW FREQUENCY RESPONSE. The sync tips are severely rounded and low in amplitude, and the low frequency components of the vertical interval have severe tilt and distortion. The net result is that receivers / monitors on the receive end will not lock up and are too unstable to use. We thought the problem might have been a bad TVRO receiver, so other satellite receivers were tried and the result is the same. All the satellite receivers tried gave the same results. If any one has any suggestions to solve the problem it would be most appreciated.

By the way, the Gunnplexer mfgr claims that the frequency response of the gunplexers is essentially DC to over 100 MHz. As I mentioned above, the video modulating signal directly at the varactor input terminal looks excellent... good sync, good vertical interval integrity. The inclusion of a pre-emphasis circuit at the output of the video driver had no effect (good or bad) on the low frequency components. Anybody got any ideas...???

It has been suggested that the TVRO receiver circuitry which is designed to remove the effect of the 30 Hz dispersion (dither) added to the signal at the satellite transmitter is the culprit, because we are not adding any dither/dispersion and the circuitry doesn't behave properly. I am also told that the 30 Hz dither was only required for a few years, and is no longer required or used, but I am unable to confirm this yet.

Source record: 114134

Is there a FAQ or other text available for those interested in Mobile Data Terminal (MDT) listening? I am interested in copying 800Mhz trunked traffic that uses the Motorolla protocols, and would like to have a PC emulate the modem/TNC if possible, but a dedicated hardware/software approach would certainly be welcome as well.
Thanks in advance, Cnfederat@aol.com.

725. Re: Anyone using Radio Shack voice recorder chip?

I have one I'll sell for $10. I bought it a while back and never got around to doing anything with it. In its original package opened only to take out the data sheet. It's a 276-1325. Price sticker on it is $17.95 but I think I got it for less.

I know this isn't the swap group but this seemed like a good place to throw this in.

[Article crossposted from rec.radio.amateur.equipment]
[Author was Steve Yee]
[Posted on 27 Feb 1995 07:45:05 GMT]

There was a brief mention about the use of a Motorola Belt Clip with
a Yaesu FT-530 Dual Band HT. Does anyone have details about
which belt clip is used ? Or is this a black hole mod mentioned
just to kill bandwidth ???

Thanks, and 73's

Steve

727. Yagi

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-01 12:36:19 UTC
From: mark1@bnr.co.uk
Message-ID: <MARK1.95Mar1123619@bhl3h20.bnr.co.uk>
Source record: 114216

Hi,

How pratical would it be to build a Yagi to operate at the 1.8GHz Euro-PCN frequencies? It has been suggested that a high gain outdoor Yagi with some low loss coax and an indoor antenna, would make a good passive repeater. The intention is to improve (or create) indoor coverage.

Would it work? How do you build a Yagi for 1.8GHz?

Thanks,

I suppose this is all true, but I have one comment to interject that I haven't seen (pardon if I missed it).

As far as long term stability, what one can do (got this from my friend WA2AAU) is to let the crystal oscillate for a few months.... stick it in the corner and forget about it. He does this even for expensive factory bought crystals sometimes (for multiplier/microwave work). It apparently is a good way to let the crystal "shake off" any particles left over after grinding. I suppose YMMV.

The point I guess would be:
a) clean it after grinding as good as you can
b) let it run for a LONG time
c) set it on frequency after that time (trim circuit, not xtal)
if you're close enough to where you want to be.

I need some help. Of course, why else would I be posting a message.
A few years back I remember reading an article about a receiver
voter based upon the noise present on the audio. I believe it was
in 73 magazine. It was either that one or QST and I can't find it
in any back issue of QST that I have. Wouldn't you know I don't
keep my back issues of 73 so I have no way of checking. At any rate,
can someone point me to ANY article on receiver voters. I'm also
interested in any personal opionions about commercially made voters.
Thanks, any information would be greatly appreciated.

I hooked it up over the weekend. Neat little chip. Non-volatile too.
You can also cascade the chips for longer recording times.

Yep; fun chip. I built a gift for a local blind ham out of one of 'em
last fall. When I get the time I plan to see if QST is interested in
a beginner's construction article on the thingy I made. (Probably too
simple for QEX! :-)

Best features for me: non-volatile storage & wide range of supply voltage.

The couple of mic's I grabbed seemed to give lower output levels than
the 400mW output amp would have led me to expect. I didn't do a lot
of playing around as I was in a hurry to finish the project. Did you
have this experience?

>frequencies? It has been suggested that a high gain outdoor Yagi with some
>Would it work? How do you build a Yagi for 1.8GHz?
>
Yep, it will work, but with 3 reservations:

a) yagi-uda's at 1.8GHz are very hard to build. The dimensions are so
small that it makes it very critical.

b) Low-loss coax. Hmmmm. If you pick up a weak signal in the
antenna, feed it thru coax, then try to re-emit it into the room,
there is a LOT of loss involved. The coax should be VERY low loss.
It's hard to imagine a passive repeater system at 1.8GHz that will
make a lot of difference unless the antenna is placed "in the clear"
on a roof or so, giving a problem of a longer run of coax. :-(

c) you may have to be very close (in the near field even) to the
indoor antenna/"repeater outlet" to make it work. Give it a go
though!

Try a helix antenna. They are relatively small and easy to set up
for 1.8GHz. They look like a flat reflector, with a spiral protruding
from the center travelling towards the target. Gain is OK-ish, but
depends on the length/ratio/pitch/frequency. Try the ARRL Antenna
Book for more info. Sorry, but I can't find mine at the mo and it's
out of date anyways. There is an interesting 4-square helix talked
about in the book, and it works very well. We used one a few years
ago for a link at 1.5GHz for a commercial job.

Good luck

Hi Joe.

Have read the book to which (I think) you refer (but I don't own a copy).
However, much of what Rohde (and Bucher) have to say in this text is covered
in Rohde's recent series in QST. Specifically;

"Recent Advances in Shortwave Receiver Design"- QST Nov 92. Also...
"Key Components of Modern Receiver Design" Pts 1, 2, 3- QST May, Jun, Jul '94.
And finally;
" Key Components... A second Look"- QST Dec '94.

My electronic construction experience is largely limited to sound system amps, pre-amps and tuners in the dim, distant past, but I am starting to get enthused again and would like to dip my toes into the QRP waters, hopefully without encountering any piranhas. At present my equipment is limited to a good digital multimeter, but I realize I'll have to acquire or have access to a frequency counter and 'scope. What else will I need? I would like to get into this without ending up spending as much as I would on a top of the line HF transceiver. I realize this is a somewhat open ended question, and that it depends on what I build and whether I go with a kit or start from bare schematics, but would appreciate some of the wisdom of the net.

As a kid we got by with a multimeter, a reciver and xtal ear phone.
The reciver served as a audio oscope and the ear phone as a scope
at audio frequencies. A light bulb was a power meter. We just tuned
every thing to max output and let it go. We were using tubes but
the solid state stuff is easier to use. We didn't have ferrite and
powdered iron cores so we rewound if cans and used air core coils.

My suggestion is if you have a reciver just build a simple xmiter
to start and go from there.

Good luck

I would like to chat with anybody who has played with gunnplexers on 10 ghz
using FM-CW modulation to measure the distance (range) of a stationary or moving object. I can hear echos, but they are buried in many harmonics and find it difficult to impossible to single out a given frequency for a particular object.
Has anyone developed a circuit using FM-CW or any other method to measure range with a gunnplexer or other form of low power at 10 ghz?

From: ka2rdo@aol.com
Message-ID: <3j63r7$7lu@newsbf02.news.aol.com>
Source record: 114133

Another consideration is a small Parabolic dish with ANY of the following feeds:
1) Dual dipole/reflector (very small, convenient to build)

2)"coffee can" style feed (using juice tin or copper flashing with probe)

3)Splash plate style feed (most difficult to build- not far off from dipole/reflector in terms of gain)

These, coupled to a fairly small dish (>40 cms) should offer decent gain without all the mechanical hassles found in theconstruction of a yagi for the uWaves.
Most of these designs can be found in the ARRL Microwave Designers Handbook, or in any number of "technical" VHF/UHF compendiums. Perhaps this is another way to solve the problem and hassle of "getting gain on 1.8GHz!

Best Wishes,

Mark, KA2RDO

David,

Bob heil made a voter for one of his systems. As i remember it
could do 3 receivers. I believe it was written up in Ham radio magazine
in the mid 1980's. As you may know Ham radio magazine is out of print.
But CQ Magazine purchased most of the Ham Radio magazine group.
You may have some luck there. Also have heard that the voter made by Doug Hall is very
good.

Gary

The Hallmark talking card is great. The stock microphone (piezoelectric
disk glued to cardboard) isn't the best. An electret mike gives much better
sound quality. Use the standard hookup, supplying DC through a resistor
and audio through a blocking cap. It sure saved my voice in the January
VHF contest...

On a related note, have any of you had you Hallmark card "slow down"?
For a while it sounded like a 78 RPM record played at 33 1/3. The
batteries were OK, too.

: appreciate any guidance you could give me.

ARRL Radio Designer is available from ARRL, 225 Main Street,
Newington, CT 06111 (tel: 203-666-1541)

Price is $150 + $5 shipping (UPS). Requires Windows 3.1, 8-MBytes of
RAM and 5-MBytes of free hard-disk space. A math coprocessor (387
coprocessor, or a 486DX or Pentium processor) is strongly recommended.

Interested in a cheap and simple keyer circuit for a beacon ?
Based on the Microchip PIC16C54RC 18 pin microcontroller. Total cost
should be less than $8. Great for Ham Radio or "lowfer" beacons.
User configurable CW speed. Can accomodate a very lengthy (or short)
message without the need to "fill" empty space as in some clocked EPROM
designs. Very little wiring required for the hardware.
I have made the file containing PIC source code and documentation
available to the public domain.

FTP to humnet.humberc.on.ca and download the file "BCN_KEYR.ZIP" in the
HAMRADIO directory.

Rick, this is exciting news! I can see the return of the
"BEER CAN VERTICAL"s of the 1950s and 60s!!

Imagine all of those "recycled" soda pop cans beieng made into
ham antennas! Why not? I mean. If this product does what you say, I
could take about 45 or 50 used cold drink cans and smolder them
together with this stuff and have me a nice 31 to 32 ft long mast
with a really broad bandwidth for 40m DXing!

RW>There is a fairly new solder available that bonds quite readily to
RW>aluminum. It melts at 750 degrees and requires a propane torch, but
RW>is just about as easy to use as regular solder on copper. Be careful
RW>with the heat, as regular aluminum melts at ~1200 or so. Use only enough
RW>heat to melt the alloy.

RW>The alloy is mostly Aluminum/Silicon, and I've seen it in my local
RW>hardware store as "aluminum solder". I imagine that it would bond to
RW>copper just fine.

RW>I saw a demo of this stuff where a nailhole was punched in the bottom of
RW>a thin coke can. The hole was repaired by "floating" a skin of solder
RW>over the hole. After it had cooled, the repair was so strong that you
RW>could not punch a second hole in it. If you persisted, the can would
RW>end up tearing somewhere else outside of the patched region.

RW>Last weekend, I repaired all my aluminum window screens which had cracked
RW>at the corners of the frame - worked "slick as a whistle".

RW>This would probably be a less messy approach than trying to solder under
RW>a layer of smoking oil.

Stephen, can you or anyone else reading this suggest some good substitutes for a pair of GE transistors used in an audio complimentary driver circuit?

They are GE-18 and GE-21 transzippers and come in the round metal cans TO-3 or is it TO-5 ? Anyway that is the same case a 2N3553 comes in.

Any helpful suggestions would be appreciated. Meanwhile I need to go rummage through the junkbox!

I am also looking for a good deal on 75 pF , 80 pF or 100 pF miniature air variable capacitors, tiny 0.1 uF and 0.01 uF decoupling caps 25V. I also need 51 pF, 390 pF and 430 pF silver mica capacitors as small as possible, and some 2.7 pF NPO capacitors. 2N4416 FET & 2N3553 transistors. Amidon T-50-6, FT-37-43, T-50-2, T-68-2

Can anyone suggest places to get these?

> with and prevent trial and error soldering if it'll be useful - it
> sounds like a great freshman-class program to model simple stuff.
> Please tell me I'm wrong!

Radio Designer isn't a radio *simulator*. It doesn't model non-linear stages, but it can help you *design* them. For example, Hayward shows you how to transform a Colpitts oscillator so that you can use small signal analysis to design it. Now an oscillator is very non-linear, but you don't need to run a Taylor series to design one. You do need to do network calculations, MAG calculations, etc that Radio Designer will handle.

It would certainly be useful to be able to model non-linear behavior, but programs to do that cost thousands, have long run times, and still only give approximate answers. Radio Designer is a design tool that, like MathCad, can help you design circuits more easily than pencil and paper methods. But it doesn't take all the work out of the process. You still have to use your own ability to understand the circuit, interpret device parameters, and divide it into logical sections for design.

Radio Designer doesn't address such fundamentals as biasing, power supply limits, or non-linear device behavior. You have to deal with those issues separately. You may think that's a serious limitation, and to an extent it is, but compared to pencil and paper it's a major step forward. You can use Radio Designer to model a mixer diplexer termination and determine reflection coeficients. You can use Radio Designer to model an input network or explore the effects of coupling coefficients on the bandwidth of an IF stage. You can use Radio Designer to develop a double stub tuner. You can't use Radio Designer to model the spurious output of a linear power amplifier, but you can use it to design an output matching network. You can't use Radio Designer to model the third order intercept of a receiver preamp, but you can use it to determine if the preamp will be stable over a range of terminations.

Radio Designer doesn't offer you a VR radio, but it can act as an assistant in designing much of the circuitry of a real radio. It's more than a toy. I really wish it would handle DC circuit behavior, but it doesn't (I can do that by ordinary hand analysis, but I shouldn't

have to. It should be able to deal with an output signal hitting a power supply rail, or solve resistor networks [though you can fake that]).

I understand why it doesn't try to deal with non-linear device parameters. There are no ordinary equations that fit most real device curves. You still have to do a piecewise fit to actual device measurements in most cases. The ideal square law isn't either ideal or square in the real world, so modeling it really wouldn't tell you much of use. The real model for non-linear devices would require a table driven numerical simulation that would result in run times so large as to make the program useless, IE you could build and test the circuit before the simulation would complete on a desktop computer, or result in simplified answers that might be untrustworthy.

I find Radio Designer a useful design aid. It can be a real time saver. Instead of tediously hand calculating circuit values, or grabbing something out of a cookbook and tweaking it on the bench, I can do a real design and have a good idea how the circuit is going to perform before I build it. I still have to tweak on the bench, but much less so, and with a better idea of what will happen when I do. (Alas, Radio Designer can also be a real time sink. I've spent hours just playing with it, tweaking this and that to see what happens.)

I found an old Wilson radiotelephone, model 1500, very cheap at a garage sale. It is crystal controlled - I called Jan Crystals in Florida - they even had the equations for sizing the crystals. I had to repeak the multiplier chain, but I got 50 watts out at 146.88...I haven't touched the receive side, so it is a little noisy, but usable. Anyway, since this is a different model, this info may be for moral support only - I called around for a tech manual, but it seems that the Wilson company was bought out / I was unable to locate anything. Good luck...

Peter:

You're talking KILOHERTZ here, right? 5000 HZ? Like, audio frequency?

I was playing with this last week, being interested in listening to distant lightning.

Here's what I did. I bought a ferrite rod from Amidon. (They advertise in ham magazines. The rod is 7.5 in long and 0.5 in in diameter. I wound it with about Two layers of about 18 guage wire (1.0 mm dia ?)m `. or about 500 turns. I used a capacitor of about .045 mfd connected in parallel with the coil to make it resonate at about 7.5 Khz. You will want to use a little more capacitance to get it to resonate at 5 KHZ . I connected this to a 15 ft long piece of skinny coax and then to a phono plug. I plugged this into my battery operated tape recorder. I could hear the signals from distant lightning just fine.

I did my recording "out of town", at least a half mile distant from a small power line. The big interference in this band is powerlines. If you are a city dweller, you'll have to get way out of town to play with 5KHx emag.

Have fun, and let me know what you get to work.

771. Variable Caps in Oil

Date: 1995-03-06 13:36:56 UTC
From: clarke@acme.ucf.edu
Message-ID: <3jf35o$4q2@news.cc.ucf.edu>
Source record: 114071
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics

I have been contemplating the problem of coming up with a 200 pfd variable cap with a fairly high voltage rating for use in an antenna tuner.

I have 100 pfd and I was thinking about putting some plastic between the plates to up the C when I thought of oil.

Could I run the capacitor in an oil bath and effectively get 2 or 3 x the capacity and probably higher breakdown?

Or does oil have an awful power factor at RF?

: : Anyone have a source of inexpensive GPS and/or flux gate boards (or
: : kits?). Reply here or to SGUCCION@OUTLAND.DTCC.EDU

Precision Navigation out of California makes an entire line of
flux-gate products. Many of these were designed to be integrated into a
GPS package. They also have a 3axis version for VR apps, but the cost is
prohibitive ($800).
For $50 though you can get one that has 2 axises and a 2 degree
accuracy.

VK4DJS writes:

I DONT KNOW THE CORRECT WAY TO REPLY TO THIS REQUEST SO I HOPE YOU WILL
PASS THIS ON TO THE CORRECT PERSON FOR ME. IN AUSTRALIA WE HAVE A COMPANY
CALLED "UTILUX" AND THEY SPECIALIZE IN ELECTRIC CONTROL AND CONNECTORS.
SOME OF THESE ARE SPECIAL OR SPECIALLY MADE. THE ONE I AM THINKING OF IS A
TYPE TO CONNECT ALUMINUM TO COPPER.THE BASIC METHOD IS TO MOUNT ONE PIECE
IN A HIGH SPEED LATHE AND BUTT THE OTHER UP TO IT. THE FRICTION FUSES THEM
TOGETHER. TO ALLOW THE ALUMINUM TO MAKE A GOOD ELECTRICAL CONNOUT ALL GASES
(AIR,ETC).WE HAVE A SOLDER PASTE OVER HERE AND I GUESS YOU
WILL ALSO HAVE SOMETHING SIMILIAR OVER THERE.I WAS THINKING WHEN I WAS
READING YOUR REQUEST THAT MAYBE SOME PASTE AND GRINDING COMPOUND WOULD BE
WHAT YOU WOULD NEED. THE UTILUX MIXTURE IS USED WHEN CRIMPING WITH HIGH
PRESSURE HYDRAULICS IS AVAILABLE.THIS SEALS IN EVERYTHING.I HAVE NOT USED
UNT ONE PIECE
IN A HIGH SPEED LATHE AND BUTT THE OTHER UP TO IT.
THE MIXTURE I DESCRIBED(SOLDER PASTE/GRINDING COMPOUND)BUT MAYBE YOU CAN
THEN SOLDERTHE TWO DISSIMILIAR METALS.HAVE FUN AND LET ME KNOW HOW YOU GOT
ON.

VK4DJS:

Thanx for taking the time to share your experiences from "down under"
with the problem of dissimilar metals and making appropriate connections.
We use a product here that goes under several trade names that is
used just for that purpose (PENETROX or NAOLOX). I've seen quite a bit
of advice on this problem that I posed to the net. The products available
here are similar to the "goo" you describe. Its typically used in the
electrical business to connect service entrance cable, which is Aluminum
to a junction box that is usually fabricated with brass. Then copper
wire is connected to the junction box and run through the residence.

I have successfully used these products in antenna construction and
the seem to work OK, albeit they are a grease and have the tendency
to allow/promote slippage. Next antenna system I work on I will
experiment with adding metal shavings to the product and create a
mixture that has a lower viscosity and try to prevent the slippage
problem. The typical residential connection box is not in an
environment that is subject to the ravages of Mother Nature as
is an amateur antenna.

I like your approach to the connection problem using torque to ensure
a secure *mehanical* bond. Early in my ham career a wise old sage use
to mutter the follwoing to this young squirt: "The best electrical
connection is a solid mechanical connection." I guess this holds
true based on your experiences. A a good mechanical connection implies

that all gases are vacated and the chance of oxidation is eliminated.
If you can please elaborate of the following:

MOUNT ONE PIECE IN A HIGH SPEED LATHE AND BUTT THE OTHER UP TO IT.

How is this done, exactly? I guess one could use a common drill
appropriatel slowed down and secured in a vice? What do you thin?

Again many Thanx & 73 de Walt - K2WK

> (single ended, tuned circuit -- not broadband).

Stephen-

According to a 1981/82 International Rectifier Semiconductor Data manual,
the two parts are the same except for voltage. Where the IRF-511 is rated
at 60 volts, the IRF-510 is rated at 100 volts. Therefore, the IRF-510
would appear to be superior.

Stephen-

The MPS-A20 may have a color dot or stripe somewhere on the body, that indicates its DC gain. From an old Motorola manual:

Min. hFE Max.
Red 40 400
White 80 400
Green 100 200
Blue 120 300
Yellow 150 300

I don't see anything else unusual about the MPS-A20. If the original part happens to have the red color code, almost any NPN transistor may work, if you can fit it in! The 2N3904 and 2N4401 are reasonably close, and should be easy to find.

779. Original Ideas Required for Radio Receiver :)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-07 02:14:55 UTC
From: misc200@csc.canterbury.ac.nz
Message-ID: <1995Mar7.141455@cantva>
Source record: 114082

Hola Everyone,

I'm a third year undergraduate at the university of Canterbury NZ, and
I need some help.

I decided to do a comms paper this year, it has one project : design
and make your own radio. Fine easy you say... except that the marker likes
original ideas.

Last year one of the students taking the course spent a fairly
substantial sum of money to build a radio complete with surround sound etc.
etc. He got about 90%, but a smart young fellow built a crystal set and got
92%. The reason he got such a high mark was because he made his own diode out
of some sought of crystal he requisitioned from physics.

So my problem is to find an original idea for a radio which falls into
these catergories (in order of importance).

1: It needs to be original, I thought of extending the idea of the
crystal set a little by making my own tuning capacitor out of some of those old
fashioned razor blades (has anyone tried this?). Someone built a 'Co-hearer'
radio last year, that got good marks. Does anyone know of any unusaul am
receivers (the older the technology the better), or know of any books
describing early radio recievers?

2: The idea has to be reasonably easy to understand by an ignorant
undergrad, and has to be reasonably easy to implement.

3: I'd prefer it if I don't have to take out a mortgage ;)

Cheers,

Stephen Simpson

PS. Please email my elec account as I read it more frequently.

The non-profit IBEGROUP (Internet Biomedical Engineering Group) is developing an IBM PC compatible 32/128/256 channel high performance biomedical data acquisition system to facilitate EEG/ERP brain research at universities and hospitals.

Launched on January 4, 1995, the group's membership has grown to about 60 professionals from 15 countries. Currently we are creating R&D teams and could use additional expertise in the following areas:

* Analog and Digital design (especially ultra low noise analog)
* Mixed analog/digital VLSI and FPLDs development
* High speed, 10BaseFL, serial communications
* IBM PC hardware/software interfacing (embedded and host IBM PC)
* Power supply (we are using inductive power transfer)
* Prototyping sites (universities/hospitals/colleges/student groups)
* EEG/ERP (Researchers who help us define desirable DAS features)

We believe this to be the first Internet based distributed product development project. We invite you to participate in this unusual and challenging project. It will not make you rich but you will be contributing to a good cause, learn some new technologies and make world wide contacts.

Your participation can range from email consultation to active R&D work. Project communications are conducted on several listserv mailing lists.

To join this project and/or learn more about it please complete the questionair below and email it to:

Herman van den Bergen, CET
IBEGROUP Project Coordinator

>Robert Heiss KO6KA

SPICE is pretty good... we have some fancy commercial versions of it here at work. The MAJOR problem with SPICE, though, is getting decent models of active devices, i.e. you want to design a class C final amp with an MRF475 transistor. Unless your version of SPICE happened to come with a model of an MRF475, you're pretty much hosed, unless you're prepared to measure complex impedances at operating frequency and translate them into a model. Even if it came with the model, you might still be hosed... who knows whether the model is any good above DC?

SPICE is great for passive circuits, like LC filters.

From: gordy@gbscomms.win-uk.net
Message-ID: <166@gbscomms.win-uk.net>
Source record: 114091

Hi all,

I'm trying to brew up fixed freq, xtal controlled rcvrs for 430-440 Mhz. The IF o/p is intended to be an FM IC (anything cheap enough), and I was wondering if anyone had any good ideas for the mixer. It has to be cheap, chearful, and repeatable. Cost HAS to be low, because they are for standby use, and the cheaper the better. 3-4 dollars is about the max we can go to.

How about some cellfone mixer IC's - any good? or are they optimised for too high freqs. Or would a ring diode mixer be better-bearing in mind that complex transformers are definitely out! (any good/cheap diodes to use?) IF will be anywhere between 10.7 and 75 Mhz, depending on the IF stage IC used.

Any ideas, observations, recommendations?

thanks-

Gordy G7HQB

Why don't you go one better and build a self-powered radio? You can use two tuned circuits with crystal detectors to form + and - power supplies to power a single (germanium) transistor audio amplifier. You will need a *high* efficiency speaker like an old horn (earphone with bell).

Oddly enough, you only need one aerial for both power supplies and the radio itself.

The first one of these I saw had a crystal detector followed by a single transistor audio amplifier.

All kinds of advantages - you listen or free, absorb the stations you hate (tune the power supply to them!) and show how clever you are!

This is guaranteed to attract attention. One caution - as the guy who wrote this up in the ARCA journal (Bud Bedker) correctly discovered, it is a good idea to included an on/off switch for when you get tired of listening to it.

How about making your own point-contact transistor and using that as
the basis for a single-transistor Rx? If someone got high marks for making
his own diode you should get even more for a transistor. 8-)

: equipment is limited to a good digital multimeter, but I realize I'll
: have to acquire or have access to a frequency counter and 'scope. What

Not necessarily. I've built a lot of stuff without needing either
a counter or a scope. Actually, the best piece of test equipment is
actually a good general coverage HF transciever. It can act as both
a signal generator and a spectrum analyzer. I'd consider the counter
to be a luxury for QRP work--notice that the popular QRP frequencies
are rather far from the band edges :-). Yeah, I know about UK novices...

Similarly, the scope is nice to have, but it probably won't tell you
all that much more than a cheap RF probe/multimeter for routine QRP
work. Not $$$ worth of info, anyway.

In my opinion, the smart way to build things is in little building
blocks. You get each little block working before going on to the
next one. You can typically test each block with the transceiver
and the RF probe/multimeter. If a block refuses to work, try
someone else's design or another approach.

792. Weather Balloon QRP Transmitter

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-08 00:10:49 UTC
From: Mark Winters <markwi@wordperfect.com>
Message-ID: <3jism9$ijo@grok.provo.Novell.COM>
Source record: 114099

I'm interested in sending up a weather balloon along with a simple transmitter. (I may send up a camera with the balloon as well, but that's another story...) The balloon could go as high as 100,000 ft. (about 19 miles). The transmitter would be used to send down information such as altitude and temperature, and would also be used to track the balloon down once it lands. I would like the transmitter to be as simple and inexpensive as possible, since I might lose the whole thing in the process.

I notice in an article in the March 95 issue of CQ (p. 104) is a schematic for a simple QRP transmitter that looks like it might do what I need. Since I'm a complete newbie at building transmitters, however, I had the following questions:

1. Would the circuit shown in the CQ article be powerful enough to send a line-of-sight signal as far as I need it to? If not, can someone recommend a source for a circuit that can do this?

2. The circuit shown in Fig. 2 of the article doesn't have values for all of the components labeled. (Maybe these values are obvious to others -- I said I was a newbie!) What capacitance value should be used for the variable (tuning) capacitor? Also, what should be used for the coil that interfaces the antenna to the rest of the circuit?

Any help or a pointer in the right direction would be appreciated. Also, if anyone knows of a group in my area (Utah) that is already doing this, could you e-mail me with a contact person?

Thanks,

Mark Winters

I had a similar problem a few months ago. I tried to mix a ~1 GHz FMTV modulated PLL source with a ~9GHz source to get a signal out, at 10 GHz. I used a modified Ku band LNB into a satellite receiver to recover the video. The video out of the receiver looked great but would NOT lock. I fixed the problem by adding a Pre-emphasis filter and optimizing the way I feed video into the VCO.

I would recommend using some of the cheaper Mini CIrcuits Lab mixers. I think you can get some of their surface mount (j-lead) versions for less than $3 US. They work great at that frequency and have 50 Ohm in and Out Z's.These mixers can be ordered dirrectly from MCL. Another possibility is to use a Signetics NE602 Chip. The mixer on this chip will work to over 500 MHz and will give you satisfactory performance. The built-in oscillator circuitry; however, will not work above 200MHz so you will have to use an external oscillator into the chip. This chip will also be easier to interface to the FM IF chips in the market due to it's higher impedances.

The double balance mixer will definitely work better because of it's higher intercept point, but the NE602 is cheaper.

I second the motion, a good reciever is the best piece of test equipment you can have. As a first project or two, one might build some of the qrp swr/wattmeter circuits that are in the Hamradio Handbook. There are also some ideas in "Qrp Classics" published by the ARRL.

Also read anything Zack writes, he's been doing this a while.

From: w9sz@prairienet.org
Message-ID: <3jjebh$gte@vixen.cso.uiuc.edu>
Source record: 114105

I did some of this with FT-243 crystals back in 1967-68 (back when I was a Novice, and Novices had to use crystal-controlled transmitters and had one-year non-renewable licenses!)

Generally, I remember I could move a crystal (40-meter) about 5 kHz up by grinding with a very fine abrasive before I lost it. It seemed to do fine for a couple kHz and then get more and more sluggish.

There was an etchant that could be used too, I believe it was ammonium bifluoride. However, it rounded off the edges of the crystal blank and gave me worse results than the abrasive grinding.

I hope this helps!

Greetings, Thomas, from a dripping wet Diepenbeek in N.E. Belgium!

I think you might give paraffin a try. Paraffin molecules are just short versions of polythene molecules, and if polythene makes a good dielectric, paraffin should do so too. Oils as such are frequently esters of fatty acids (you guessed - I work in a chemistry department!) and as such have polar groups which can give rise to HF losses. Ordinary paraffin should be OK, don't know how the medicinal grade differs.

Hope this helps, 73

Check out the upc2756 and upc2757 downconverter IC's from NEC. These
are 2 GHz chips which have a local oscillator, mixer, and mixer post-amp,
all for under $2.00! There are other chips in the family which have up
to 70 dB of post mixer IF gain and AGC.
The only problem for the experimenter is that these are fine pitch
SMD parts...a little difficult to handle, but not impossible.

Hi all - I found a source of VERY reasonably priced parts for building
your own electronic equipment:
KA7QJY Components
Box 3893
Logan, UT 84323
(801) 563-5173

You can send him an SASE for a catalog, or I think he can FAX
it to you.

His prices are about half what everyone else charges, and he caters
to QRP builders, but also has many other parts available.

I once had the same problem when designing a 3.6kW (twin 4CX1000A) linear amp. I found a spray can from RS in the UK. Cant remember what it was called, but it had an ability to withstand something like (guessing) 50kV /mm. Its RF propeties were said to be good. It was black and had to be sprayed on then heated for some time (24 hrs for best results) at about 100 deg C. I used a lab oven at work, but remeber thinking it was the sort of temp you could get in a domestic oven.

The amp has never worked too well, so I cant say how good the cap was at very high RF voltages. It was an output coupling cap and had no troubles at 800W out.

I considered oil, but a spay can seems much easier.

There have been several schematics and design projects in QST over the last few years. Sorry I don't remember the issues.

You're right that the ICOM interface price is OUTRAGEOUS! The interface is simple. The electronics is a Maxim 232 chip and a voltage regulator as I remember. Even with all new parts it should cost less than $20.00

>someone else's design or another approach.

I agree with everything Zack says (wow, a first). In particular,
I find a counter practically worthless and rarely heat mine up.
Your commercial transceiver will do double duty to determine
frequencies, or you use the spectrum analyser. However, a scope and a
spectrum analyser are *so* useful, I'd make an effort to acquire them.

Good ones are showing up on the surplus market, and at hamfests, at
really attractive prices these days. Even if it's a huge old boat anchor,
as long as it works, it'll be mighty handy on the bench. A calibrated
signal generator is also useful, and I've found them at hamfests for
as little as $25-$45 dollars (tube type table benders), but a commercial
transceiver equipped with a 30 db tap, a dummy load, and a step attenuator,
can do just as well. You can build all those bits yourself.

There are usually ways around the lack of a particular piece of test
equipment, but having good test equipment makes things so much nicer
that you'll tend to work at the bench a lot more. (You'll also curse
all those spurs you didn't know you had a lot more, but the rest of
us will thank you for finding and fixing them.)

: Could I run the capacitor in an oil bath and effectively get 2 or 3 x
: the capacity and probably higher breakdown?

In theory, yes. This has been done in some old military/naval gear.
I know of one semiconductor kilowatt linear that was immersed, heat
sinks and all in a sealed, oil-filled container with external fins.

Bubbles and contamination can limit breakdown voltage to less than
dry air rating

: Or does oil have an awful power factor at RF?

No, at least not the right oil. Look at the ARRL handbook section on
oil-immersed dummy loads for oils.

What does go wrong, is that the oil can nicely lubricate the sliding
contact of your capacitor. Just where you don't want an oil film, you
need wipers with plenty of contact force

Very very messy... ;-)

Cheers
David

Well, this is true for the UK, BUT in Belgium, "BE", paraffin is
solid Paraffin Wax, used for medical specimen preparation and making
candles.

: Hola Everyone,

: I'm a third year undergraduate at the university of Canterbury NZ, and
: I need some help.

: I decided to do a comms paper this year, it has one project : design
: and make your own radio. Fine easy you say... except that the marker likes
: original ideas.

Then you must think of your own idea, or else it won't be original.

That other bloke's surround-sound job was probably little more than
the result of a lot of money, a lot of hours work, and the diligent
reading of published designs/applications notes. Creativity level: low

The guy with the crystal set was smart enough to choose something of
a sensible scale, and did it in a way that is unusual today. Duplicating
his effort even with a home-made capacitor is now not very original.
Your marker is doing his best to help you, he is trying to get you to
explore, not follow.

If he said "make" rather than "build" or "assemble", what proportion
of components should be homebrew?

What sort of lab equipment do you have access to? think
physics/mechanical more than electronic..

Your choice should be bold, not gung-ho, so that even an unsuccessful
attempt is meritorious rather than foolhardy.

It's the 50th anniversary of the freeing of Colditz, some prisoners of
war built their own radios out of whatever they could get their hands
on. What difference could modern knowledge make?

Espionage agencies put radios, usually simple transmitters, into
innocuous objects. You could elect for modern components and let your
sense of humour loose on choice of housing.

Could you make a radio using technology of an age earlier than the
discovery of radio waves? (I've just had a crazy image of how the
Spanish inquisition would have made a variable capacitor, and a
point-contact transistor from ancient Egypt... I might just have a go at
this myself, just for a laugh, and as a conversation piece for the local
radio club)

These are examples, but, I'm sorry, I've spoiled their originality by
suggesting them. Go and read some old books and magazines, go looking

for inspiration in unlikely places. Cooking up something entirely on your own, without anyone else helping is great fun. Turn over stones, kiss frogs, there's inspiration out there and no-one can ever predict where. The right idea will make you smile.

Cheers
David GM4ZNX

Zack Lau Replied:
Similarly, the scope is nice to have, but it probably won't tell you
all that much more than a cheap RF probe/multimeter for routine QRP
work. Not $$$ worth of info, anyway.

I agree with Zack, but I would say it differently. I own 2 scopes, but I NEVER use them for RF work. They are handy sometimes for simple digital and audio type things. I have 200 MHz Digital Storage scopes available here at work and I find the RF tools (like the spectrum analyser) of 100 times the worth of the scope. The scopes most hams can afford (including me) just aren't good past about 20 MHz, so your money is better spent elsewhere.

I agree with Zack about the other equipment, especially the general coverage receiver. When money got tight and I sold ham stuff, the receiver was at the bottom of the list of things to sell. I can recommend good surplus one like an R390 made by Collins (or its DC cousin the R392). They are pretty accurate considering the technology involved. The newer synthesized ones from Radio Shack and similar places (Sony, etc.) are pretty good also plus you can accurate digital readout of frequency (hence no need for a counter).

From my conversations with the people providing the software and my experience with Microwave CAD systems like EEsof-Libra and HP-MDS I think you have much more than you realize in ARRL-RD. Yes, it would be nice to have some of the things people have asked for like schematic capture and non-linear models but even the the tools I mentioned have had their problems in providing these thing and it does not come cheap: I run a Sun Sparc-10 with 64 meg Ram and 500 meg disk, have a dedicated IIS group to take ca
re of software rev uploads and system crashes and have had lots of factory training for the software. You think you can get that for 150 dollars? My understanding is that Arrl RD offers the full linear modelling capability but less of the features of the original software from which it is derived. It isn't a fancy front end for the equations in Solid State Design by Hayward and Demaw but a real simulation engine with very sophisticated capability.

Does such a thing exist ? What I want to do is run one length of high
quality (ie, very low loss, ie, expensive) feedline up the tower
and be able to run on these bands simultaneously. Relays would not
be feasible for this reason.

Is this something that could be built as stripline filters on a board ?

I'm not looking for off-the-shelf, commercial solutions neccessarily--
just comments on feasibility.

Thanks !

>above DC?
>
>SPICE is great for passive circuits, like LC filters.

True, but the same issue regarding good models still applies to
LC filters. To accurately model L and C networks, you need to
include the parasitic reactances that are present, such as the
series L and R in a practical capacitor and the series R and
shunt C present in an inductor. For example, the notion of a
"J0" capacitor is a capacitor in which the series parasitic L
resonates with the series C at some particular frequency.

At HF, you can probably ignore the parasitics, but anything
higher and you can't ignore them.

English is not my own language, but may I quote "The Condensed Chemical
Dictionary", 7th Edition, edited by Arthur and Elizabeth Rose; Reinhold
Publishing Corporation, New York 1966. (I have this oldie by me.)

"
kerosene. See kerosine.
kerosine (kerosene). (The spelling kerosine is preferred by ASTM and ACS
publications.) A distilled hydrocarbon from petroleum or shale
oil, having a boiling range from about 150-300 degr. C.
Currently the most important uses are as fuel for jet engines,
denaturant for alcohol, and as a heating fuel. Formerly used
as an illuminant. Kerosine is also often used as a solvent for
cleaning purposes; also in emulsions as an insecticide.
...
paraffin distillate. A distilled petroleum fraction which, when cooled,
consists of a mixture of crystalline wax and oil.
...
paraffin, liquid. See petrolatum, liquid.
...
paraffin oil. An oil either pressed or dry-distilled from paraffin
distillate. Liquid petrolatum is also known as paraffin oil.
...
Uses: Floor treatment; lubricant; when purified, medicine.
paraffin oil, white. See petrolatum, liquid.

petrolatum, liquid (white mineral oil; paraffin, liquid; paraffin oil,
white).
Properties: A colorless transparent oily liquid, a mixture of
liquid hydrocarbons; almost tasteless and odorless even when
warm; sp. gr. 0.828-0.880 (25 degr.C) (light), 0.860-0.905
(25 degr.C) (heavy); soluble in ether, chloroform, carbon di-
sulfide, benzine, benzene, boiling alcohol, and fixed or vola-
tile oils; insoluble in water, cold alcohol, glycerin.
Derivation: Distillation of high boiling (330-390 degr.C)
petroleum fractions.
...

Grades: Technical; U.S.P. XVII (as mineral oil, formerly liquid petrolatum, heavy); N.F. XII (light); F.C.C. (as mineral oil, white).
...
Uses: Medicine, cosmetics; dispersants, diluents, etc. in plastics manufacture; compressor and textile lubricants;
dispersants for reactive compounds such as metal hydrides;
catalyst carriers; in foods as binder, defoaming agent, lubricant, release agent, fermentation aid, protective coating.

That's a rip, the crystal set was one of the first and most primitive receivers, hardly any originality there. The other guy probably just copied a design too, but at least it was more involved. But Ok, it gives us an idea of what the instructor is looking for. Let's see if we can impress him without going overboard on the historical reenactments.

How about a selective TRF receiver that uses *no coils*. That should baffle him for a moment. Hint: the answer begins with "g". Let's see if you've learned anything yet.

While I agree that the spectrum analyser is the single best RF tool,
I disagree strongly as to the worth of a GP oscilloscope. That's
generally the *first* tool I reach for, and the last one I put down,
when I'm working at the bench. Not only is it a better voltmeter than
a voltmeter, but it's also a window on waveforms when I'm looking at
stage performance, and it's even useful for harmonic detection, though
seldom to the degree offered by the spectrum analyser. I use it for
modulation analysis, of course, in both the analog and digital domains.
How else are you going to see an eye pattern but with a scope? Or
display a trapezoid pattern or two tone test? Once you go beyond a
raw carrier, the scope is one of your most essential tools.

Scopes good up to VHF, like the Tek 465A, are going for $300 or less
at hamfests these days. And even an old boat anchor Tek 545 is good
to 40 MHz, and can likely be had for the asking. (Makes a nice shop
heater too.) Now sure, I use a Tek 2465A on the bench, it's usable
to 600 MHz, but that's because I got it at a bankruptcy sale for under
$700. My old Tek 453A is nearly as useful, and they're going in the
$200 range now. I'd advise anyone interested in building, or repair,
to invest in a good GP scope, and learn how to use it. It's the most
flexible tool on your bench.

Gary

The most flexible tool you have is between your ears, of course,
but unless you've fallen asleep, it isn't on the bench. :-)

Tony,

You will require a UX-14 internal interface. It changes a non standard parallel port
to a bi-directional serial port at TTL voltage levels. Then you will need a level converter
like Icom's CT-17

It is a good idea exept for one thing. The computer is a notorious generator
of RFI, radio frequency interference. Sometimes when I am trying to listen
to HF (amatuer radio shortwave), I have to turn off my computer because
of the interference it generates. This would be one drawback, perhaps
there is a way to overcome this problem. But it might not be easy.
Good luck with your project.

>It looks like the PLL is unlocking. The signal at the output of the

Hi Michael, forget the directions in the manual. Adjust the frequency
to mid-scale pot while transmitting at mid-frequency (146?). The voltage
drop while transmitting is enough to upset the PLL so simply adjust the PLL
while transmitting into a dummy load. Note the unlock points and set it for
half-way in-between. IMO, the receive PLL will lock OK after that step. If
it doesn't, find a mid-way point between receive lock and transmit lock.

The Ramsey kits are fully functional once they are adjusted properly and
modified in accordance with the QST article. I have built half a dozen
of them and learned a lot doing it. If you want full frequency coverage,
email tlcdhconsult@delphi.com for details. Don, KE6AJH, will serve me
a double-scotch for every kit you buy. :-)

regarding the moving of crystal frequencies, when I worked for a small precision crystal manufacturer (of hc-18, etc type mount crystals, not FT-243), we would, for lab experimentation purposes, modify crystal frequencies by injecting iodine gas into the crystal holder can.

This involved several NO NO's, which shouldn't be done on crystals you REALLY need to depend on, unless you have no other choice (such as stranded in an igloo with nothing but a soldering iron, syringe, some iodine crystals, and a radio).

1) break into the can by desoldering the little corner of the crystal near the top where the solder closed the can while in a vacuum environment (forget ever getting it to a vacuum again).
2) Using some iodine crystals in a coarse syringe, while monitoring the operational frequency of the quartz crystal, inject the vapor from the iodine crystals into the can.
3) STOP well before you get where you are intending to go.
4) seal the can once the frequency has apparently stabilized.

What you are doing, in effect, is loading down the silver on the crystal with oxidization, and thereby changing the frequency. You could do this by just breaking the seal, and waiting for the effects to occur, but the iodine speeds this up. Just like the FT-243 when you load it up with pencil lead (there is no silver plating on FT-243 blanks as far as I have ever seen), you can go too far and kill the oscillation. But if you have a TON of crystals to play with, you can get quite good at it. As part of engineering, I was not invoilved with operations on the production floor, and we did this ourselves. But to modify a crystal a couple of KC, and then put it in a vacuum chamber to stop the process dead, the production people would use this as a fine tuning measure. I do not know if tis is still done- this was over twelve years ago.

good luck es DXOM

>"Recent Advances in Shortwave Receiver Design"- QST Nov 92. Also...
>"Key Components of Modern Receiver Design" Pts 1, 2, 3- QST May, Jun, Jul '94.
> And finally;
>" Key Components... A second Look"- QST Dec '94.

I have the Rohde and Bucher book and it is quite dated compared to
Rohde's more recent articles. If you are building an HF receiver, it
is probably best to stick with the the Rohde QST articles, one by Jacob
Makhinson (sp?) (QST within the last 18 months) and Communications
Quarterly articles in the last two or so years. Also, don't forget
the Rohde articles in QEX (also in the past year).

If you really want the book, you could try writing Rohde at his CBA to
see if he knows of sources for his book. Or, find him on the air. I
have heard him hang around 14,180 kHz or so. I think I have worked him
on 14.260; his second home is on some choice North America IOTA or
something :-).

838. TDA1072 Radio IC Info Sought

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-11 19:45:29 UTC
From: tomrice@netcom.com
Message-ID: <tomriceD5AK7t.9wB@netcom.com>
Source record: 114038

The TDA1072 IC appears to be an interesting "radio on
a chip" as presented in some articles in English wireless
magazines.

I have a meteor forward-scatter receiver project going and would
like to try this device, but have not found any hard info,
such as the manufacturer and suppliers in the U.S.

Any information on this device would be appreciated.

Thanks, WB6BYH

I belive that drawing a small dot on one side of the xtal wafer would
lower it a few KHz as well. Also, a ll dot of solder has much the sma
same effect (but is more prone to destroying the rock). There was an
article in QST back in the '60s about this...sorry but don't remember
the issue. GL

$*$*$ 20 Weak Signal Challenge (HAM Post) - Now $30 $*$*$

Three weeks have passed since the original posting of this challenge.
During that period, the Web page was accessed over 1000 times.
The weak signal recording has been listen to and processed by
many. Several operators using their best audio filters have been
able to copy my call. And yet, a correct identification of the calling
station has not been made. I am increasing the amount offered to $30
and will continue to escalate the prize until someone cracks the problem.

Details on the challenge can be obtained from my Web page:

http://www.webcom.com/~af9y/

The winner will be announce in the UseNet groups carrying this post
and my Web page.

Final Note for those trying their own signal processing techniques:

Many have asked about the WAV file format used for the
A/D recording. The format is a PC Windows standard which
contains 43, 8 bit-bytes of header (which can be thrown away)
followed by a consecutive series of 8 bit A/D data. The sample
rate was 8192 samples/sec.

Good Luck,
de Mike Cook - AF9Y

For about $500,000.00 you should be able to find the equipment necessary to measure such minute particles.
Of course you will need to build a steril labe environment first for about $5,000,000.00

If one automobile passes your house anytime withing about a 8 month period your tests will be totally inacurate.

IG>Idiom Press, Box 1025, Geyserville, CA 95441-1025
>Price $45 + $3 s/h to as US mailing address.

IG>Do they have a fax number - and do they take credit cards?

The address as you present it appears to be correct. However, I cannot
confirm the last four digits on the ZIP code ("-1025"). Only the forst
five are published.

The current pricing indicated $48 U.S. for stateside shipping and $50
U.S. for DX shipping, postpaid.

No FAX phone number is published and a recent advertisement indicates
"NO CREDIT CARDS". Sorry.

This is an excellent keyer. I have built several and used many. If you
are familiar with the KC Keyer, popular among contesters, this is what I
would call the little brother to the KC-1 keyer. It's designed by the
same two engineers, but marketed differently. Many usable features.
Smooth, seamless, keying. And quite easy to use. I was fortunate
enough to be one of the beta testers of v2.x of the firmware, so a
(small) bit of N0SS in there, too.

854. MC 1350 AGC resistors ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-13 01:33:39 UTC
From: mfranks@eagle
Message-ID: <3k07dj$1ui@news.ais.net>
Source record: 114054

I have been looking at several schematics with ganged MC 1350's
in the IF chain. In the AGC leads there is a resistor in series
with the control voltage, one resistor is approx half the
value of the other resistor---Why ? , am I missing something here ?
Is there a voltage divider or current divider for some reason ?
I do know there is a minimum voltage needed for the thing to work.
Please respond via email----mfranks@ais.net Thanks !!

855. Ham gear for sale

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-13 02:06:00 UTC
From: chris.smart@canrem.com
Message-ID: <60.5063.3290.0N1D5258@canrem.com>
Source record: 114055

Hi. I have the following equipment for sale. If you are interested in any of the following, want to make an offer, ask for more information, and so on, here's how to contact me:
Mail addresses: Internet: email to chris.smart@canrem.com, Fidonet: netmail to 1:229/15, Rime: private/routed mail to ->crs.
Phone (voice): 519-756-9389 (if I'm not around, just leave me some voice mail)

1. 15-20 amp power supply.
I have a 15 amp homebrew DC supply for sale. This thing is better built then most of the commertial supplies I've seen/used, is very solidly constructed, doesn't get more then slightly warm when supplying 15 amps at 13.8 volts DC.
I didn't build it, but I can certainly atest to its high-quality. The four big transistors at the back are rated at 5 amps a piece, so it'll probably put out close to twenty amps if pushed. DC voltage is also variable; (currently set to 13.8).
I'm looking for about $80.00 Canadian funds for it, since its in absolutely great condition, and was hardly used. (price is negotiable)
Reason for selling: I am saving up for a decent acoustic guitar, a dualband HT, and other things.

2. Ten-tec Argosy II

Yes, I'm parting with it, after 6 years of great performance.
Features: extremely small solid-state rig; great beginner radio for people with a low budget, perfect for mobiles, a great backup rig for emergencies or up at the cottage.
- 5 or 50 watts ssb and cw,
- transmits upper and lower sideband, cw, (automatically ofsets transmitter when switched over to cw)
- transmits and receives on 80, 40, 30, 20, 15, and 10 metre bands. (10 m is split into four band selections, 28.0-28.5, 28.5-29.0, etc.)

- great notch filter for eliminating carriers
- digital readout for frequencies, power/swr/signal meter,
- comes with Ten-tec power supply, d-104 desk mike that looks aweful but is a perfect match with this radio,
- also comes with voice readout for frequencies, (great for white-caners like me)
Reason for selling: I'm just not interested in keeping this thing around any more. I have almost lost all interest in HF, and will buy a better radio when I get back into the low bands. Furthermore, as I mentioned above, I need the money for other things.
History: For the first year after I purchased this radio, I was

constantly replacing fuses in the power supply, and the radio was pretty warm even with almost perfect swr readings. Then, the voltage regulator went for good in the power supply, blowing the two big transistors in the finals. $138 later, the supply and radio were fixed, and I have had no problems since. No blown fuses, no overheating problems, etc. It works great, except for the following minor problems. The plastic knob on the
mode-change control can be removed by simply sliding it off its post. There is no longer a knob on the notch filter control, but this could be easily remedied. Also, the RIT control needs to be lined up again. In other words, when the RIT control is in the middle of its range (transmit and receive are on the same frequency supposedly), transmit is down the band about 1.5 KC's from where the receiver is. I just turn the RIT to correct this, but its annoying having to have it permanently set wrong.
I'd like $450.00 or best offer for this rig, power supply, voice readout, d-104 mic. I still have the manuals and paperwork as well. If you don't want the d-104, I'll probably just throw it out as its so beat up.
73, de ve3 sht.

856. Sangean ATS-803A for sale

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-13 02:06:00 UTC
From: chris.smart@canrem.com
Message-ID: <60.5065.3290.0N1D525A@canrem.com>
Source record: 114056

Hi. I have a Sangean ATS-803A general coverage receiver for sale. Its
the same as the Realistic DX-440.
Its a portable general coverage receiver that receives 150 KHZ-30 MHZ
continuous coverage, receives am sideband and cw, also receives fm and
fm-stereo from 88-108 MHZ.

- can be run from wall adapter or batteries
- internal, telescopic whip, or can be connected to an external antenna
- din plug can be used to hook this radio to a tape recorder,
- with headphones or with your stereo (through the radio's 1/8 inch
headphone jack) you get FM broadcasts in stereo
- rf gain, bfo, bass, treble, balance, and volume controls
- ten memories for your favorite stations
- direct frequency entry via number keys 1-0
- can tune in steps with knob or up/down keys
- will scan for stations/signals
- built-in clock with alarm
- lock switch prevents accidental key presses
- also has narrow/wide receive switch for narrowing bandwidth

I have the radio, the manuals/paperwork for the radio, and the
wall power adapter for the radio. Unfortunately, I cannot
sell the radio with a pair of stereo headphones, but all you
need are your standard walkman type, or anything with a 1/8 in
plug.
This radio is in fine shape, except for a broken telescopic
whip antenna which needs to be replaced. (most of the antenna
is there, but a couple of the end sections broke off a year or
so ago)
Reason for selling: I have one of those great little Sony's,
so don't need this radio.
I'm going to leave the asking price wide open on this radio.
I paid $275.00 a few years ago for it, but have no idea what
they're going for used these days.
Please reply via any of the following methods:
Internet: email to chris.smart@canrem.com
Fido: netmail to 1:229/15
Rime: private/routed mail to ->crs
Phone (voice): 519-756-9389, (just leave a message if I'm not
around)

Thanks,
73, de ve3 sht

857. Dualband HT HELP??

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-13 02:06:00 UTC
From: chris.smart@canrem.com
Message-ID: <60.5064.3290.0N1D5259@canrem.com>
Source record: 114057

Ok, once I sell my small HF rig and power supply, I plan on buying a dualband HT. I haven't had any experience with any 2 m or 70 cm equipment for years. The last handheld I owned was an Icom IC02AT; I loved it. I'm looking for something with the following features:
- direct frequency entry via a number pad, (I can't handle those little switches or thumbwheels as I can't see the display)
- 4 or 5 wats output on 2 m and 70 cm
- a hot little receiver that doesn't get constantly overloaded with intermod (I'm in a city of about 80,000 people, so the intermod problems aren't extreme here yet)
- at least 10 memories per band
- CTCSS capability on both transmit and receive, (very important on receive)
- extended receive capability, (not just the ability to make the display go out of band on receive). This would get rid of the necessity for a scanner to monitor the weather stations and a few other frequencies.

Also, what are the battery options on HT's these days? It would be nice to get something better then a nicad pack, such as the NiMH batteries available in most notebook computers these days.
Oh, by the way, I was originally considering just getting a 440 MHZ rig to avoid the conjestion and interfearance on 2m, but I figure I may as well just get an HT with both bands for what its worth.
Please let me know what you're using, approximately what its worth new, what you like/dislike about it, etc. Can you get antennas better then a rubber duck for these things that work on both bands?

Thanks and 73, ve3 sht.

: de Scott N6UUH

You can make J-Pole antena for dual band(2M/75cm) like following.

```
|<-1/4*75cm->| |<-- 1/4*2M -->|
-------------+ ----------8---+ -
| | 6cm
-------------------------+----------------------8---+ -
|<--------------------- 3/4 * 2 M ----------------->|
|<------- 3/4*75cm ---->|
->| |<-
feeding point
Nomally 5 cm, adjust for
matching(SWR)
```

Good Bye....

859. paraffin/kerosene etc

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-13 08:47:38 UTC
From: dcadd@luc.ac.BE
Message-ID: <9503130847.AA28592@alpha>
Source record: 114059

Greetings, folks, from a gloriously sunny Diepenbeek in N.E. Belgium!

I had no idea that a simple word like 'paraffin' could cause such confusion! W7EL is correct in his explanation. I repent in sackcloth and ashes for not making clear what I intended in the first place.

What I actually meant by 'paraffin' was a low molecular weight liquid composed of hydrocarbon molecules being apparently devoid of any reactive chemical properties, paraffin, from the Latin 'parum affinis', i.e. without affinity. The stuff which the medical profession pour down people's throats to relieve various bowel disorders should do fine, you probably can get it from a drug store (says he displaying his knowledge of Colonial English) and it probably carries the approval of the U.S. Pharmacopoeia, so it can't be all bad.

Next to that, whatever Roy has described as 'kerosene' will probably do the job. (But I thought they fed that to jet engines ?! Maybe it's the same stuff)

I agree with David Stockton's comments re. sufficient contact pressure - I confess I hadn't even thought of that problem.

Stephen Parry is indeed correct when he says that paraffin to a Belgian is a solid, I've just asked one of my colleagues in my best Flemish, but I'm an ex-pat Brit (well, actually my Mother's family were Camerons of Lochiel . . . etc etc etc)

Hopefully that clears the air on this one. Whew!

73,

Duncan ON/G0UTY G-QRP 8117

In Britain, the term 'paraffin' by itself means what is termed 'kerosene'
in North America. The stuff the physician might use to grease the
internal ways is known as 'paraffin oil' in Britain and 'mineral oil' in
N.A. The solid 'paraffin wax' in Britain is commonly just 'paraffin' in
the U.S. All this does make for a certain amount of confusion. To an
organic chemist the term 'paraffinic' refers to saturated hydrocarbons,
but kerosene certainly includes unsaturated as well as saturated hydro-
carbons, just to add to the confusion.

All of which is a bit wide of the mark when it comes to this newsgroup.

A good practical introduction to ladder filters is in "W1FB's Design
Notebook" by Doug DeMaw, published by the ARRL. The ultimate book
on filters, of course, is by Zverev (Handbook of Filter Synthesis),
but it is out of print. All three copies in our library at work seem
to have been stolen, so it must be good!

[Article crossposted from uk.radio.amateur]
[Author was steve roberts]
[Posted on 13 Mar 1995 23:17:25 GMT]

Greetings,
I wish to set up a general decoding station i.e. weather satellite,
general fax/rtty etc using a 486 pc and Linux to control the various
receivers and perform the decoding. Does anyone have any unix progs
source code or ftp sites that may be useful??
I will probably have to hack the Linux kernel :-(, any suggestions?
Has anyone used the Maplin dsp weather satellite interface?
My basic setup would be an AR3030, FRG9600, dedicated weather sat
receiver and interfaces as required...including the Maplin interface.

Cheers Steve Roberts

Source record: 113970

I've been following this thread for so long now, that I've finally decided to throw in my 2 cents....

Sometime, a long time ago (maybe in the sixties), I saw an article about making a "variable frequency crystal". The technique was based on the old FT-243 crystals which were packaged in a compression type holder. In this crystal type, a square quartz blank is sandwiched between two flat electrodes, and a constant electrode pressure is maintained by a compression spring which fits between the sandwich and the metal cover of the assembly. The resonant frequency is a function of several mechanical influences, including the spring pressure on the quartz sandwich.

The unique idea was to vary the resonant frequency by varying the electrode pressure. A hole is drilled in the center of the metal cover of the FT-243. A brass nut is soldered over the hole on the outside surface. A headless screw is threaded into the nut so that it contacts the compression spring inside the assembly. A small knob is affixed to the outside protrusion of this screw. Now, as the knob is rotated, the pressure on the quartz blank is varied, and the resonant frequency changes. Voila! A Variable frequency crystal.

Of course, the frequency change is small (several hundred Hz to a couple KHz), but this was the next best thing to a VFO in the days of "rock-bound" novice operation!

>
>: I decided to do a comms paper this year, it has one project : design
>: and make your own radio. Fine easy you say... except that the marker likes
>: original ideas.
>

I've been following this thread for a while now, and it seems that eveyone
is suggesting ideas to do with old/obsolete technology. Why look to the past
for *original* ideas - look to the future!

How about using a uP/DSP chip? or writing some really fancy code for say,
a soundblaster card, and mix the RF down to audio using software?

The future is reliant on original ideas - sure, look to the past for pointers,
but don't base your project on the past - comms is a futuristic area - go with
it!

Apparently, a few years ago, Mini-Circuits did not want to deal with the amateur and hobbyist market and gave small order customers a lot of trouble...
Well... Things have changed. Maybe new management, who knows? About six months ago, Mini-Circuits took out full, back-page adds in several hobbyist and amateur magazines. They packaged a dozen or so designer kits with prices less than $100.00. And they even published an 800 number only for amateurs and hobbyist. I have never seen this number listed in their adds for the commercial market. For all appearences, Mini-Circuits is bending over backwards to serve the amateur and hobbyist markets. Of course, I have misplaced the mags with the 800 numbers, so call the regular number and ask for the 800 number and while you're at it, have them send you their designer handbook. It's as big as an issue of Computer Shopper. Sometimes it is best to go straight to the source first...

I called ICOM - They happily sent the schematic for the computer interface - it was either free or really cheap. All it really does is convert the rs-232 signals to ttl levels - for connection to the radios. With that thought in mind, Ive taken an old PC serial comm card - and have rewired the rs-232 level shifters to convert the rs-232 back to ttl on the card - and have soldered the necessary cable to connect to the radio directly to the card. I haven't had a chance to try it yet - but I will soon - Also have to write some code to control the radio. Anyway - thats my approach for handling the ICOM computer interface.

Good luck and 73's de Dave, kd6pro.

I have been buying parts in small quantities from the local Mini-Circuits distributor in Chicago (Cain-Forlaw) and have received OUTSTANDING service from them all along. They have been more than willing to sell me ONE DBM if that is what I needed. I have sent larger orders too, they have a price break for more than 5 MMIC's and they also have some very good cheap chip caps for bypassing.

Sorry, out of MAR-3's at the moment...need to order some more!

I've been a pilot for a few years now and recently got into ham radio.
I am interested in buying a handheld that can TRANSMIT and receive in both
AVIATION and ham frequencies.

While a number of handhelds receive AM (aviation is AM), they are unable to
transmit AM. This includes a few brands that are CAPS modifiable.

I was wondering if such a handheld unit exists or whether a knowledgeable
person was able to homebrew such a radio from an existing product.

An unlocked 2 meter HT, like my DJ-580, makes a decent signal generator
for 137-138MHz using a dummy load and low power output.

I am setting up my Yaesu 747 to be the IF for a transverter. The rig uses some small coax with "Weird Yaesu coax connectors" to connect the RF board to the power amplifier and to connect the antenna to the receive-in on the RF board.

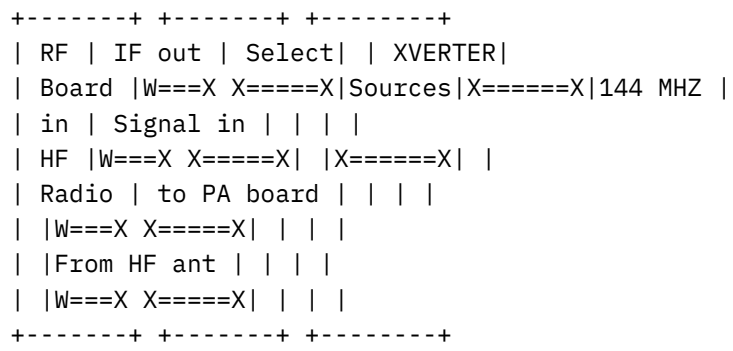
I called Yaesu and a very friedly fellow took my $$ and promised to send me a couple of pieces of the coax with the ends on them. I'd like to cut them in half, and put some sort of reasonable connectors on but, I am wondering about signal loss.

My hopes are to build a source selector so that I can use the setup as:

Simple HF radio (IF out routed back to PA board, HF antenna routed to Signal in)
Simple 2M radio (IF out to Xverter, Signal in from Xverter)
Satellite mode A (IF out to Xverter, Signal in from HF antenna)

without haveing to take the lid off all the time (the connections to the RF board look fairly fragile), and without having to spend 15 minutes connecting identical looking cables to the wrong places so that I can just miss a good satellite pass.

I'm thinking of something like:



Where W represents a "weird connector", and X represents a reasonable connector. The back-to-back connectors will be on the back of the radio. I need them because the coax with the weird connectors is short, and the connectors are "supercrimped" on and don't look like they will come off in any state to be put back on, and Yaesu does not sell them unattached. [sigh]

Unfortunately, to use it as a simple HF radio, the output signal must go through EIGHT connectors (SIX of which I'm adding). This has me worried about the losses from those connectors. My _ARRL Handbook_ does not have a table of connector losses, and I'm hoping someone out there does,

or has a better idea.

I could replace the back to back connectors with four very small PC board boxes, soldering the coax together inside. I could also directly wire the source selector to the cable. Or am I just worrying about nothing??

Thoughts???

Dave,

The transformer will be not really a problem. At least here are
several companies who will wind one for you at a reasonable price.
You would be talking about 150 A at the input. BTW, I do not
know of a voltage source wit 13.8 V at 150 A. usually more like 12 V.

The problem will be the switching devices, you would need power mosfets
with an increadibily low on-resistance...

>How much do I need to spend on an RF signal generator to align a homebrew
>137-138MHz reciever????, what is a good name brand???, Where can I get
>one?

You mean you're actually going to *buy* one?

other options

1: use a scanner with a 10.7Mhz or 21.4 Mhz IF (ie a cheap one). Tune the scanner either 10,7 (or 21.4) Mhz above or below the 137Mhz freq your rx is tuned to. use the radiated LO signal as a weak signal source.

2: build a simple xtal oscillator to provide a signal source

3: use an hf transceiver working into a dummy antenna. transmit on a freq that has a harmanic relationship with the 137 Mhz band (eg for 137.5MHz, try 15.278MHz or 12.5Mhz - pick the higher hf freqs if poss to give a higher harmanic o/p)

I've been doing this for 5 years now, even though I have access to some *very* good eqpt - it's often quicker than setting up the pro gear :)

The most recent QST (March?) has an article called 'Put Away Your Pencil" that includes a circuit to give
computer control of you Icom HF Rig. I imagine that the interface is exactly the same for your R7100. It is,
after all, only a voltage level converter. All of the electronics fit in the DB-25 housing, and it is powered
by the PC's serial port. I built it and adapted it to my Yaesu FT-840, and it works like a champ.

It cost me about 20 bucks to build, an $80 savings over Yaesu's converter.

losses thru any connector at hf are normally nothing to worry about, in my opinion.

>>I could replace the back to back connectors with four very small PC board
>boxes, soldering the coax together inside. I could also directly wire the
>source selector to the cable. Or am I just worrying about nothing??

I think ur just worrying about nothing. Here's what I did many moons ago:-

1. Fit a switch in the logic cable that disables the pa board (see below)

2. Snip the mini-coax leads in half (both tx and rx) and attach them onto the back of a couple of bnc connectors or similar on the back of the rig. (if you do it carefully you won't even cut the braid) I use BNC connector because they are easy to connect up when they are at the back of the radio when you are all fingers and thumbs, but make a note of the positions of the TX and RX connectors so that you don't "brown-hole" it and stuff the RF out up the RF in hole etc

3 Either swap the bnc leads to connect up the kit or fit a 3-switch to select the direction/source required.

Note that you don't have to worry about the switching rf away from the pa if you use the logic line to disable the pa altogether ..... hang on, I'm getting the service manual out......
it's a 3 wire lead from the main board to the pa unit:-
J06 on the main board, pin 1=gnd, pin 2(centre, the one to fit a switch in) TX9V, pin3=13.5v this connects to...
J03 on the pa unit

this is what you should have....

<------------\ /------------>
TXmain bd \ / paTX
\/
bncTX pa unit (now switched) (please, no jokes
about class D etc :-)

<------------\ /------------>
RXmain bd \ /
\/
bncRX paRX

---------------------------------13.5v
pa sw/ off
J06-----------/ --------------------TX9v J03 pa unit
main bd on
---------------------------------gnd

If you get problems with breakthrough on the receive side either manually disconnect the main hf antenna out of the back of the pa unit (PL259) or fit a coax switch in the feedline.

NOTE
You can also use the bnc o/p as a low level, synthesised, all mode signal generator. If you have general coverage TX enabled it's very useful on the workbench, but turn the pa off before you start! I'm a UK class B licensee so I've cut the TX9v lead altogether, so I can't make any cock-ups when servicing commercial kit.

The o/p from the TX drive is quite low, so it may need a stage of amplification before driving a transverter.

Good luck

Gordy

>Frank KM1Z

There is a there is a ham transceiver on the market that is built on a pc board.
I forget the manufacturers name but I have seen it demonstrated, and it works.
The board is very well shielded to avoid the interference. The transmitter
output
is 100 mw. so you use it to drive an external power amp.

>
> --
>

There was an article in QEX about 18 months ago which used a stack of toroid cores. This was for use from a regular line voltage, rather than 13.8v, but the power rating of the transformer shouldn't care.

For your application, the extremely high input currents would be a real problem. The switching transistors would be far more of an issue than the transformer.
I havent got as far as building one yet, but I have been scratching at a design to power my 2 x 7289 1296 amp for portable use (1100v @ .5A) and am having a hard time coming up with a circuit which wouldn't destroy itself too easily.

If you make any progress on this, I'd certainly be very interested to hear your results; and I suspect several others would be also.

Q-Dope is Polystyrene which is dissolved into some solvent usually an acetone. You can buy it at most electronics outlets which cater to TV repairmen and the like. It is sold under the name Q-Dope, by more than a few companies.

Actually I have known people who have made it by taking model glue (airplane glue) and thinning it out with more solvent.

Hope this helps,

You won't find one that is both, I don't believe. As you know the aviation freqs operate AM, and have to type accepted for that use. I have yet to see one company that offers any FM features in one of their aviation band handhelds.

If you're using your own aircraft, you should invest in getting a 2m rig in the aircraft. Even if you use a handheld with an amp.

>I am building a simple direct conversion receiver from W1FBs QRP Notebook
>and he mentions coating the oscillator inductor with polystyrene Q-Dope.
>
>My question is, What is this stuff, What does it do (i.e. do I need it),
>and where can I get some?
>
>Thanks in advance.
Q-dope is just polystyrene disolved in a solvent. It is used to coat a coil
to block moisture absobtion on the wires which might lower the Q. It used
to be sold by General Cement Company and was listed in the Newark and Allied
catalogs along with the lubricants and contact cleaners. I don't know if it
is still available. You could make your own by disolving clear polystyrene
is a solvent like mineral spirit or trichlorethylene (use the clear uncolored
polystyrene, not the cloudy high impact polystyrene, it has rubber in it
which will raise the loss).
You can paint it onto the coil or dip the coil in it.

What would you need an amp for? The shuttle doesn't need one and
I don't think a private plane would fly as high.

It's just plastic goop that holds the turns of wire in place. This is moderately important on the oscillator coil - very slight movements of the wire will send your oscillator drifting off into space.

Polystyrene is specified because it doesn't kill the Q of the coil by absorbing RF. "General Cement Q-Dope" is the trade name, and many electronics mail-order houses sell it. I've had good results using plain old polyurethane varnish, the type you seal up wood with. Measured Q remained above 200 on the one coil I tested.

>a low current high voltage winding, and probably a feedback
>winding for the transistor oscillator)?

Ouch!
2.5kv at 500mA is 1250watts

Even if the inverter were 100% efficient this would mean

1250/13.8=90.6 Amps @ 13.8v

Assuming 90% overall efficiency (probably reasonable)

90.6/0.9=100.6 amps form 13.8 volts

and power dissipation in the inverter of 10*13.8=138 watts.

Even assuming you can get the current at 13.8 volts (presumably from a
bank of car batteries or something), it is going to require very careful
design to handle this kind of current. Good luck!

Duncan Cadd (dcadd@luc.ac.BE) wrote:

: I had no idea that a simple word like 'paraffin' could cause such confusion!
: W7EL is correct in his explanation. I repent in sackcloth and ashes for not
: making clear what I intended in the first place.

Our venture scout group on an expedition to the French/Swiss border
regions tried (no-one spoke fluent French, Italian or German..) to
buy "Paraffin" for their Primus type cooking stoves... they thought they
were doing well until the shopkeeper started producing blocks of wax :-)

Aviation turbine fuel has been christened "Avtur" to sort out
possible confusions with turboprop and helicopter engines. "Avgas" is
for piston engines.

Avtur, Kerosine, British (just hum anything by Elgar..) paraffin,
Diesel fuel and some light heating oils are all very similar.
Differences in additives, and the care in removing water and
contaminants are important for engine longevity. Here in the UK, the
government forces the addition of dye and a chemical tracer to
everything but road-legal diesel so that people using low tax fuels can
be prosecuted. Agricultural-legal Diesel is 1/5 the price of the road
stuff...

Kerosene/paraffin/Diesel is NOT a good thing to immerse things in,
it can prove corrosive due to contaminants.

I'd recommend either the medical stuff, Aviation turbine LUBRICATING
oil (not the fuel), or proper transformer oil (Not PCB based 8*( )

Fuel oils and car lubricants have all manner of nasty additives, and
are used in quantities/applications that don't force extreme
cleanliness.

Cheers

> Is there a magic solution to this problem ? :-)
>

There are lots of possibilities for reducing your interference.

Starting from the interference source: make sure ALL the case screws on your PC are tight. This makes a big difference. Route the power cord as far from the receiver as possible. Use a power filter between the PC cord and the wall (Tripp-Lite ISOBAR or similar). Plug the receiver into a different outlet, if possible. Separate the receiver and the PC as far apart as you can. Loop the signal cable connecting the two units through a large ferrite toroid several turns. If you are using an unbalanced antenna line, make sure it is well shielded.

If you still can't copy weak signals, you may have to change either the receiver or the PC. I have found that older PCs and newer rigs have less interference problems. Now I use a GENUINE IBM PC (4.77 MHz) and an IC-751A and have no interference at all (except on harmonics of 4.77 MHz!). Newer, faster, cheaper computers generate much more RFI.

Good luck ... Pierre (no, I don't speak french :-)

919. Re: MC 1350 AGC resistors ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-16 14:48:28 UTC
From: tayloe_d@sat.mot.com
Message-ID: <1995Mar16.144828.18159@schbbs.mot.com>
Source record: 113918

The AGC voltage on the MC1350 is specified as useful in a range from 5 to 7 volts, 5 volts being maximum gain (50 to 60 db), 7 volts being minimum gain (up to a 10 db net loss).

Although everyone talks AGC voltage (using the standard 5K resistor to feed agc to the MC1350), what is really important is the AGC input current. Max gain is 5v, at a current of 0.1 ma, Min gain is 7v at 0.2 ma.

However, more important than this is the fact that at max gain, the *noise figure* of the device is 6-8 dB (50 to 60 MHz), whereas at 30 dB gain reduction (about 6.25v), the noise figure is way up to *22 dB*, extremely noisy indeed.

Therefore, if two MC1350s are ganged together, it is prefered to run the first one with less AGC gain reduction than the second in order to keep the overall noise figure for the IF amp reasonable. This is usually done by increasing the resistance for the AGC feed to the first amp (10K) so that less gain reduction is done by that stage, and more is done by the second stage where noise figure is no longer a consideration due to the gain of the stage(s) in front of it.

In article <60.5064.3290.0N1D5259@canrem.com>, chris.smart@canrem.com (Chris Smart) says:
>
<snipo>

Your reasons for wanting 440 vs. 2 meters interest me since my experience tells me that RFI and QRM and intermod are much WORSE on 440 than on 144 in the "big" cities I get to once in a while (Albuquerque, Denver, Phoenix).
This is, I assume from my commercial 2-way background, because there is MUCH more repeater activity in the commercial 450-470 band just above the 440 ham band than in the 150-174 MHZ VHF public service band. There are just almost NO VHF commercial repeater pairs available while there are lots in the 450-470 band. Thus, there are lots of community repeaters and individual repeaters on the mountaintops and every tall building generating RF of varying levels 450-470 while most of the commercial VHF activity is simplex, with few mountaintop transmitters. Thus, while HAM activity in most areas is heavier on VHF (2M) than UHF (440) the interference and garbage I hear are worse on 440, at least when I get close to a city.
Now, to answer your question, the only rig I PERSONALLY know of that fills all your requirements easily is the Kenwood TH-78A or 79A, but the keypad entry involves more than just dialing in the right frequency via the keys. I always thought thumbwheel switches were better in this regard (that is, being able to find what frequency you're on without seeing the numbers). But no current rigs I know of have thumbwheels anyway. Matter of fact I believe you MUST be able to see the screen display on current rigs to do much of anything, especially frequency and tone entry etc.
I don't think it has 4-5 watts either... there are several single band ht's offering that kind of power but I don't know about dual banders.
In the Southwest we don't have the crowding problems on 2 meters that drive many to 220 and 440 so the main reason I MYSELF like 220 and 440 is the availability of remote bases and repeater linking on these bands. Being able to work HF SSB, high power long distance 2 meters, etc, all with a shirt pocket FM HT, is lots of fun. That's what I value 220 and 440 for. Just my opinion. 73.....

Q-Dope is just polystyrene disolved in a sovent that will evaporate in air. It is used to hold the windings on a coil form. Polystyrene does not adversly effect the Q of the coil.

If your coil is mechanically stable, you don't need to use it.

It is manufactured by General Cement (GC) and can be purchased from electronics parts distributors.

Tom-

Polystyrene is used because it has a high Q over a wide range of frequencies. It seems that some other dielectric materials are "frequency selective", and can even get hot at their worst frequency.

An example of a poor dielectric choice for RF, is ordinary PVC pipe. At some frequencies it is good, but not at others.

Jon-

Although I have seen the "2p2" shorthand nomenclature before, I don't think it is common. The letter is located where a decimal point would go, and indicates what the units are. In your examples, 2p2 would be 2.2 pF, 2u2 would be 2.2 micro Farads and n39 would be 0.39 nF (which equals 390 pF). Resistors listed as 3k3 would be 3.3 k Ohms, 4k7 would be 4.7 k Ohms and 5k6 would be 5.6 k Ohms.

I would guess that 470R was 470.0 Ohms, and it might be used when a more precise value was needed. There is certainly no need to add the ".0", for a 5 or 10 percent part!

As far as "which cap to use", I think the 2p2 is exactly the same capacitor as the 2.2 pF, et cetera.

I think you can make the stuff yourself by dissolving polystyrene in a
suitable solvent; 1:1:1 trichloroethane would probably work quite well,
as it evaporates quickly, if you can get it. Make sure you have plenty
of ventilation if you do this.

This doesn't work very well. You get a much better dielectric if you get
a glass of toluene and dissolve styrofoam cups into it until you get the
appropriate thickness. I've been using it for years with good quality into
the VHF regions.

I was thinking about the 12 (or 24) volt to kilovolt trasnformation as a way to avoid 220 VAC. A couple of big car batteries can put out a kw or more intermittently.

I was thinking of working at high frequency, 100's of kHz like a switching powere supply. This would make the tranformer small. To avoid the need for high current transistors and in the attempt to find off the shelf components, I thought of the ubiquitous PC power supply. They contain transformers that go from 220 v (when in 220 mode) to 12 volts. Ten of these run in reverse and wired in series would give you a couple of kV. The PC supplies are rated at 200 watts or so, so 10 would also supply a kW or two without major overload. You would have to hope the insulation was good for the voltage, though.

I'm a long way from tryinng this, however, and wiring ten sets of transistors/transformers would be a bore. Depending on the switching supply compoenets, if you were operating on 160m, you might have a power supply working at a higher frequency than your final :-)

the "-1025" is simply the box number tagged on the end of the zip code, for quicker sorting at the destination post office. It isn't essential if you don't want to use it.

I need some help building a 2800 Mhz -> 2 M Receive converter for the radio telescope project I am working. I just received the ARRL UHF and Microwave Projects Manual and they basically tell you how to build up several kits from Down East Microwave but don't really give the meat and potatoes on how to design one yourself. Is it possible to modify the the 2304 MHz Converter or the 3465 MHz converter to 2800 Mhz by just changing the LO and trimming some micro striplines on the board?

Is an interdigital filter a converter?

Does anyone have a design or resource suggestion on how to build an xvrtr.

Greetings, Jon, from a wet and miserable Diepenbeek in N.E. Belgium!

The placing of the symbol, whether k, p, n, u or whatever, does away with the decimal point. Thus, 3k3 = 3.3k, n47 = 0.47n, I'm sure you get the idea. Good luck with the construction or what-have-you!

> Thanks, Bruce WB6IZG

There are a number of commercial converters available fairly inexpensively,
but it's not hard to roll your own. The hard part is in the software driver
to tune the dot clocks of the VGA card to approximate NTSC timing. You can't
get RS-170A without a full standards converter (expensive), but you can get
something close enough to work with most VCRs and TVs.

Nope, not a stupid question at all....

>I have a schematic listing several components with typical R values like 56k,
>470R, etc. but some are listed as 3k3, 4k7 and 5k6.
>
>Q1 = what does the 4k7 and 3k3 style of notation represent?
>

4700 and 3300 ohms respectively.. (4K + 700 and 3K + 300; or 4.7K and 3.3K)
The reason for this nomenclature is that decimal points sometimes are lost
in printing, wear, or photocopying. By printing 4k7, you can usually always
make out the characters easier.

>The caps are the same with some listed as 1nf, 10uF, 27p, etc. but others are
>listed as 2p2, 2u2 and n39.
>
>Q2 = what does the 2p2 and n39 style of notation represent?

Same type of thing... 2.2pF and .39nF

>Q3 = how do I know which type of cap to use?
> (might this be what the notation represents)

The value syntax is covered above. If you mean disc cap, electrolytic,
tantalum, plastic, etc. that takes some assumptions. If the caps are
used in an oscillator, use the best disc caps (npo,etc.) or plastics
you can find. If they are used in audio, filtering, etc. I use cheaper
disc caps, electrolytics, etc. Temperature stability is more important
in an osc. section than in audio. Bulk C is more important in filtering
unwanted noise from a supply. Accuracy is more important in an RF
filter section. Good luck Jon.....

943. VHF amp low output mystery

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-17 18:55:18 UTC
From: jdc@cci.com
Message-ID: <D5LLw6.CBC@sunsrvr6.cci.com>
Source record: 113944
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

A friend has a 2-meter 120-watt power amp that appears to have very little gain. When measured with a SWR meter it shows about 1.2 times the input reading. Replacing a couple of the fixed caps with trimmers gave a little more gain, but not much. The input SWR is fairly low.

It draws 12 amps from 12 volts, about normal for that amp. It generates a lot of heat, too. There is almost no current draw when not transmitting; it is a class-C amp.

Based on the current draw it seems like something is going on. Could there be some terrible mismatch on the output? Perhaps all the power is reflected back into the transistors and turned into heat. After all, 12 amps * 14 volts is almost 170 watts, and it looks like we're getting 40 or so watts out for 25 watts in.

Any ideas? It was a $50 special from Dayton ("works great"), and it would be nice to get it going.

73...Jim N2VNO

Archive-name: radio/personal-intro
Revision: 2.1 1994/11/01 03:50:23
Posting-Frequency: posted on the 15th of each month

This message describes the rec.radio.amateur.*, rec.radio.cb,
rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet
mailing list counterparts and complements. It is intended to serve as a
guide for the new reader on what to find where. Questions and comments may
be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October
1994 to add the discussion of non-Usenet mailing lists and streamline most
of the history discussion, and to change the moderator information for
rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became
progressively higher. First one by one, and then as part of two
reorganizations, what was once one group became many. In the process,
developments elsewhere on the net were reflected in the groups as they were
created, most notably the change to place all of the ham radio groups in one
hierarchy.

The collection of newsgroups continues to grow as more people join the net,
and as more topics of discussion gain volume, I expect to see more groups be
created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the
notable exception being rec.radio.swap. There are also a few mailing lists
that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them,
and not to the groups that aren't. The whole idea of having different
```

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

945. Pin out for ICL 7107 LED Volt Meter

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-17 21:04:30 UTC
From: rdewan@uhura.cc.rochester.edu
Message-ID: <1995Mar17.210430.12815@galileo.cc.rochester.edu>
Source record: 113946

Could some one please send me the pin out for ICL 7107
that is used as a voltmeter a/d 7 segment led driver.
I ordered the chip from digikey to incorporate in a
digital display swr meter. I have not been able
to locate the data sheets or pin-outs. The CMOS cook
book has most of the pinouts, but no details on how the
segments map to the IC pins.

Any help would be appreciated.

>spending as much as I would on a top of the line HF transceiver. I

I built a qrp transciever for 40 meters, my only eq. was a reciever, VOM
and a soldering iron. Qrp transmitters are quite simple and therefore
easy to construct. If you have a reciever already, try a small crystal
controlled transmitter for starters, you can use the rx to verify the
transmit freq, and the meter to determine the transmitter power.
It's not as hard as you think, don't be afraid to go ahead and homebrew
it from scratch. If you think you need to go the kit route, Ramsey
electronics is one that I would reccomend. You can call Ramsey at
800 446 2295. No, I am not affiliated, just one of their satisfied costomers.
BTW, my 40 meter rig was "from scratch".

Larry Kenan <larry.kenan@SanDiegoCA.NCR.COM> writes:

>There is a there is a ham transceiver on the market that is built on a pc board.
>I forget the manufacturers name but I have seen it demonstrated, and it works.
>The board is very well shielded to avoid the interference. The transmitter
>output
> is 100 mw. so you use it to drive an external power amp.

sounds cool, with the right kind of sheilding I'm sure it can work. I don't
mean to say it's impossible, in fact, the pc would be ideal for controlling
a radio of any kind. I thought about using one of the digital synth chips
on a PC card a couple of years ago, an idea for a reciever in 73 mag
inspired me, I did not carry it out however. The older pc's seem to be
better for use as computers in the shack because of the slow clock speed.
The original XT had a clock of 4.77 mhz. although it may create rfi, perhaps
not as much as something newer, also, the older machines may have had better
shielding. I am curious to know the name of the "transciever in a card"
manufacturer. 73's.

Ramsey electronics has a great kit that will transmit in **Stereo**, any audio that you feed it. It will output about 20 mw, this may not sound like much, but it's enough so that you can hear it on a "walkman" anywhere in my house. Call them at 800 446-2295. I don't work for them, but I have this kit and I am rather impressed with it.

^^^^^^^^^^^^^^^^^^^

I've worked for a few firms here in europe where it it the ONLY approved way of annotating diagrams. I fell foul of this (once) and still have an "official bollocking letter" to prove it. It's quite common in the UK, and I use it 99pc of the time myself. The reason the decimal point or 1000 grouping is represented this way is that decimal points sometimes "disappear" on poor photocopies, faxes and litho reproductions. The letter form is much easier to make out.

Gordy

PS when putting them into a calculator, for example 2p2 becomes 2.2e-12
the "pico" takes the place of the decimal point, and aslo signals the "e-12"
some students take to this easier than 0.0000000000022 F (or thereabouts)

Hi Brian,
I too am kicking around some ideas for a RT. Wonder why you picked that
freq? Are you thinking of the neutral Hydrogen line? I would be
interested to exchange ideas with you. As for your question regarding
the filter, it is a type of cavity filter that utillizes metal "cans"
with rods or "digits" which protrude in the can to establish resonance.
Should be some info in the ARRL handbook on them.

Thanks for the right name. Hexand and benzene are not the same compounds.
Benzene has three double carbon bonds and froms a ring. Hexane has
no double bonds and is a straigh chains. Benzene also crystalizes at
5 deg C.

This is getting pretty of base for a ham group.

958. 32kHz oscillator drives me nuts

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-18 21:14:07 UTC
From: Sbehrens@contech.demon.co.uk
Message-ID: <262116784wnr@contech.demon.co.uk>
Source record: 113956

Hello,

my apologies if this is the wrong group: This has really nothing to do with radio. It has to do with an oscillating circuit that I am trying to homebrew, so I hope I am not entirely off-topic.

The situation is this: I have before me a counter that should count from 0 to 15 and then wrap around at a frequency of 32kHz. The problem is: It doesn't. For some reason yet unknown to me the oscillator part of the thing is oscillating at a rather higher frequency, around 100kHz in one layout, and something in the MHz in another.

Here is what was originally suggested by the article:

```
32kHz C, 22p
+--|O|--+--||---+
| | |
| | |
+--|>---+--|>---+--|>--->> to CLK of LS161
| LS04 | LS04 | LS04
| | |
+--===--+--===--+
470R 470R
```

This swings somewhere in the MHz range (don't remember exactly where). The authors of the gadget readily admitted that they had never tested the timer and that it did indeed not work. So, a friend gave me this advice:

```
+--|>---+--|>---+--|>--->> to CLK of LS161
| HCT04 | HCT04 HCT04
| H
| H 220R
| |
+--===--+
| 10M |
| |
+--|O|--+
| 32kHz |
| |
= 2.2n = 22n (both C)
| |
GND GND
```

He particularly insisted on the use of HCT instead of LS. Well, it behaves closer to the mark (somewhere around 100kHz), but it does not

do what I want it to do either. And yes, I have checked that the crystal I use is indeed rated at 32kHz :) (32.768kHz to be exact). In fact, I now have 4 copies of this sitting around, and they all behave weirdly ...

Since I haven't done anything on this for a while and have now moved a couple of k-miles away from said friend, getting help from him is becoming increasingly difficult.

So, if you have any clever suggestions to make, a book to read, a totally different circuit that you know works, anything, basically, then _please_ let me know. This thing is "driving me up the pole", as a collegue of mine would have it.

Yours

Soenke Behrens

Please! Hexane is *not* the same as Benzene !!
They both have 6 carbons, however in hexane they are in a signle line,
while in benzene they are in a hexagonal ring. The resulting chemical
properties are quite different.

I'm a bit new to homebrew stuff, so this is probably a stupid question. But I'll ask anyway.

I have always heard of Heath and Heath kits. I see Heath equipment advertised on the net. But I have never seen a Heath ad in 73, CQ, QST, or anywhere else. Does Heath still exist? Are they still making kits? If so, what is their address? Or is there just older equipment that's still kicking around (according to the stories I've heard, Heath stuff aged very well).

Any info would be appreciated.

Heathkit has been out of the consumer and radio amateur, etc., electronic business, Will, for a few years now. I think they are still making computers and some other stuff. Apparently the actual putting together of a piece of electronic gear had become such a small part of its total cost that there was little financial advantage to putting it together yourself. Back in tube days, all of the time spent in hand wiring and soldering was a major part of the cost, and, if you did it yourself, you saved significant bucks.

Apparently there is a place which sells Heath replacement parts, etc. Maybe someone could dig that up for you if you need it.

If I were just bashing this out, my first try would be:

```
32khz
------|O|-------- to your divider
| 1/6 7404's |
-|>*-----|>*--
| |
-/\/\-
1k
```

Do it on a breadboard, get yourself a pot and a trimmer cap, and make sure it comes up right when you switch the power on it cold. My usual mistake w/ these is wiring the 7404 backwards... As you can see, there are a million variations on these little clock circuits :). Fox might actaully make a one piece for 32khz if you can't seem to get your own to work. BTW, many crystals will function at two (or more!) frequencies based on how you bias/impedance_match them.

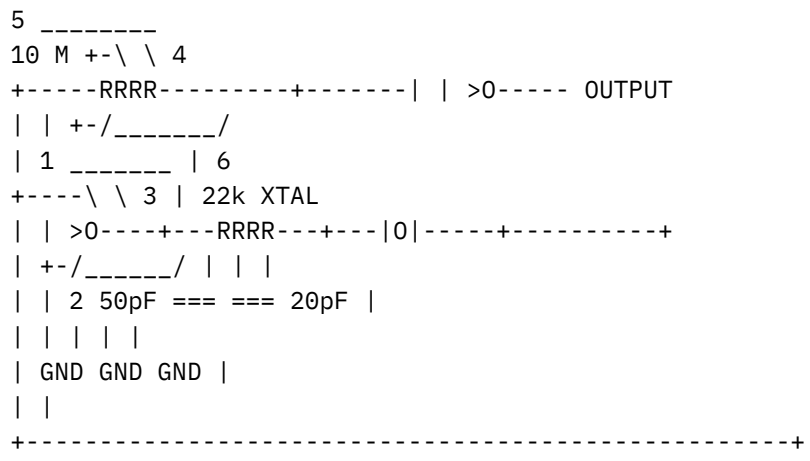
For low frequency circuits I would use CMOS such as the 4001, which is
inherently low-frequency. Any inverter with a 10 Meg resistor across
input to output will function as a high gain amplifier, and will oscillate
nicely if you give it any feedback. With a 4001 a good configuration is:



This is from Don Lancaster's "CMOS Cookbook" (Howard W. Sams publ.)
If you use the "A" series such as 4001A, you can drive a TTL input
directly. A "B" series gate will drive one LS-TTL input.

: Q3 = how do I know which type of cap to use?
: (might this be what the notation represents)
: Thanks in Advance!
: Jon

Jon...
3k3 = 3.3k and 3p3 = 3.3p and n39 = 0.39n

In most places throughout the world you will find
3k3 used in print to avoid the possibility of the
(dot) being lost by the printing and/or recognition
process... which would cause the value to be confused
with 33k. All British and German publications that
I have seen do it that way. There is nothing that
tells you about the type of part. The alphanumeric
character represents the order of magnitude multiplier
and is positioned where the dot is intended to be.

Knowing what type of part to use will depend on how
much $$$ you want to spend and how stable or reliable
the device needs to be... how well it needs to perform.

Hope this helps.

Kurt... n2tte

I'd love to do that, but I don't have anything to meter this (lack the
hardware) ... all I can do is fire up my timer, read it out with software,
and see wether what comes out makes sense (i.e. wether a 5 second loop
really takes 5 seconds). If I don't get anywhere I guess I will have to
try and find someone with the proper gear to display the frequency that
actually comes out of the circuit.

> there are a million variations on these little clock circuits :). Fox
> might actaully make a one piece for 32khz if you can't seem to get your

Yeah, there are a million variations. I'd like to be able to not go
through them all, though :). What's Fox? Some US company, I guess? Being
in the UK, that wouldn't be too helpful, alas. :) But thanks for the
thought.

> own to work. BTW, many crystals will function at two (or more!)
> frequencies based on how you bias/impedance_match them.

As I have found out .... *sigh*.

Anyway, I shall give your design a try as well and let you know what
it does. Thanks.

Cheers
Soenke

973. For sale: ham stuff

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-19 21:02:00 UTC
From: chris.smart@canrem.com
Message-ID: <60.5144.3290.0N1D6888@canrem.com>
Source record: 113874

Ok; I'm going to try this again, this time giving less extraneous details.
If you want to know anything further about the following gear I have for
sale, contact me at:
Internet: chris.smart@canrem.com (prefered)
Fidonet: netmail to 1:229/15
Rime: private/routed mail to ->crs

1. Homebrew Power supply, 15-20 amps, 12-15 volts DC (can adjust
voltage); very solid construction, runs very cool most of the time,
better then any commertial jobs I've used. $75.00 Canadian or best
offer.

2. Ten-tek Argosy II, very small 50-watt HF rig; 80, 40, 30, 20, 15, and
10 meters ssb and cw. In great shape; comes with Ten-tek power supply,
beat up but great d-104 microphone, voice readout for speaking frequency
on display.
This is the Argosy with the digital display. Great for mobiles, a backup
rig, a simple station up at the cottage, etc. Asking $450.00 Canadian,
I'll lower the above homebrew power supply to $50 Canadian if I can sell
it with the Ten-tek stuff.

3. Sangean ATS-803A general coverage receiver. 150KHZ-30MHZ and 88-108
FM broadcast, (fm stereo with headphones). 10 memories, sideband or AM,
direct frequency entry, runs on wall adapter or d-cells. This is the same
as the Radioshack DX-440. I'd like $190.00 Canadian, or best offer.
Note: I'm selling the power supply because I need the money; I'll
probably regret it some day. I'm selling the Ten-tek stuff because I
*REALLY want an FT-530, and I'm selling the receiver simply because I love
my little Sony receiver and don't need another swl receiver around.

ATTENTION FRANK E. LOUNSBURY (forgive me if I spelled your name
slightly wrong): I responded to your offer to buy the Ten-tek stuff and
15 amp supply via Internet email, and then didn't get anything back.
Please email me again when you read this if you're still interested.

Chris.

> Steve,WD0GSQ

I built the Ramsey 6M kit and was generally impressed. I found that the parts were well organized, the instruction manual was thorough (included a theory of ops in each section) and top quality parts are utilized in the design.

I was able to build the kit and do the testing and alignments at the end of each section in about four serious evenings.

So far, I've not been able to get full output power and I'm having trouble finding the problem. All other sections gave me no problems.

I highly recommend buying their companion enclosure.

Happy building,

Dave

Message-ID: <1995Mar20.162043.48520@ucl.ac.uk>
Source record: 113887

Many VHF amps use push-pull for extra power. Some designs for single tube amps use grounded screen (ie cathode below ground, control grid even more negative). Is anyone aware of a design for an RF amplifier, using two tubes that uses grounded screen, push-pull? If so, please let me know.

I have tried to design such a beast, using a pair of 4CX1000A tubes. It never did work too well and are wondering if I am attempting the impossible. The problem may be the difficulty of matching into the high input C of the 4CX1000A at 144MHz. I know many designs using one tube of this type.

David's quite right here. To confuse things further, there's
cyclohexane, which is C6H12, straight hexane (various isomers)
which is C6H14, and benzene, which is C6H6. Best naming
conventions leave hexane as a straight chain and its isomers
with unambiguous names... but IUPAC naming isn't necessarily
used on the street.

Don't rule out the bearings as the source for the noise. This was a common problem in the HeathKit tuners
I serviced as a factory repair tech. Many times the bearings would dry out and cause noise while tuning
across the band. I don't know if this will apply to an antenna tuner but it might be worth a try.
Regards,
Monty

>noisy indeed.

At 30dB of gain reduction, why is the noise figure of the amplifier
that important? Assuming the gain reduction is due to a properly
designed and functioning AGC loop, wouldn't the input signal be
so strong that the fairly high NF wouldn't be an issue?

Source record: 113896

I put a couple of these on the HP network analyser some time ago to see how good they were. The bottom line is that they aren't very good. The Q at 32 KHz is poor and there are MANY spurious responses near the desired frequency. Given the awful quality (from an RF standpoint) of these, you need to have a circuit that is VERY CLOSE to what the manufacturer specifies.

One option that comes to mind is to put a low pass filter (R-C) in the feedback loop. This would presumably reduce the tendency to oscillate at 100 KHz.

: out for 25 watts in.

I don't know what the output configuration looks like, but it sounds like
there's power being consumed in the final(s), but it isn't reaching the
output connector. Check to see how the output is coupled to the final(s) -
it might be a transformer winding gone bad, or a bad coupling cap. Check
any inductors in the power supply to the final(s), too.

The circuit differences between an SSB radio and an FM radio are
so substantial that you should banish any dreams of trying to make
a conversion. If you are just academically inclined, you would be
better off building a new unit from scratch.

Practically any HF receiver ever manufactured (including your
11 meter receiver) has plenty of sensitivity. Adding a preamp usually
only serves to make the receiver more overload prone. If you wish to
dig out the weaker signals, your efforts will be better rewarded
by improving your antenna system.

1005. 49MHz walkies to 6m use??

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-21 02:39:36 UTC
From: c594911@showme.missouri.edu
Message-ID: <3kle98$12gs@news.missouri.edu>
Source record: 113904

I've been toying with converting (or trying to anyway) a Radio Shack walki-talkie for use on 6 meters. Model 60-4021 is a set of radios that operates on 49.840. Assuming a crystal change is possible without recalibrating or anything, I still need to raise the power a bit. The units output only 25mw (at 9volts) and i would like to get the output up to 5 watts or so. Any ideas about building an amp for this?

My eventual goal is to work a repeater on 52 MHz here in Missouri. Any help or pointers to plans would be appreciated! I'll post my results here if it ever gets done <grin>.

I don't think you will learn very much from constructing a kit, if you
are starting from scratch. I'd build a simple "crystal" Rx to start with,
and work your way up from that. Add a simple AF amplifier, then an RF
amplifier. Then use the resultant TRF Rx as the IF amplifier and AF
stage for a superhet, by adding a mixer and local oscillator. This
type of Rx will only be suitable for AM, of course. You could substitute
a regenerative detector for the diode detector and alter the frequency
coverage, enabling you to listen to CW and SSB amateur transmissions.
This was basically how I started 30 years ago.

Alternatively, a simple direct-conversion Rx, would enable you to listen
to amateur transmissions straight away, although you probably won't learn
as much.

The ARRL Handbook which you should be able to find in any good bookshop
is full of the basic "building blocks" for the types of receiver mentioned
above. Your local amateur radio club should also be able to provide you
with lots of advice and assistance.

I have modified the single channel Radio Shack 49 MHZ hand held that I
believe is similar to yours and it is a painless operation if you have
changed crystals before. You might need to mount the transmitter crystal
on it's side due to space limitations. Radio Shack got around this by
using a low profile crystal case to clear the speaker. The bigest
problem is the need to mount a connector so that you can couple the rf
out of the rig to a amp. There is very little room inside
and very little suport if you remove the antenna. I have not made a amp
for my rig as of yet but like you am looking for a proven design to up the
power on the unit. Another idea I have is to make the squelch adjustable
even with a pot that can be set once. The squelch is quite high in my unit.

>
>> Is it possible to convert FM over to SSB? <snip>

Well, it CAN be done, but probably not in the manner (cheap and
inexpensive) that you're probably hoping.
You can take the audio output from an FM receiver and use it for
audio INPUT to a SSB transmitter. That's what I do in my remote
base (444.65 and 224.94 control inputs) system here in Los Alamos.
But as far as making an FM rig over into a SSB rig it it pretty
rugged to contemplate. Adding an FM limiter/detector board to the
receiver wouldn't be too hard but the low level transmit audio
amplifier circuitry would be about all that could be used on transmit.
You'd have to add a balanced modulator, SSB filters, and separate
linear amplifiers to get the resultant low level SSB signal up to a
usable transmit level. I certainly agree that other than adding an
FM detector to the receiver only I wouldn't contemplate such a project.
Much easier to buy a used CB SSB transceiver and add a much-easier-to
build transverter (available in kit form from Hamtronics if desired) to
get it on useful frequencies.

Big Nose Chuck. Chuck worked for Lockheed and developed the BNC connector for use in VHF and UHF applications. The regular UHF connector (developed by Uncle Harry Frankforther) never worked well at VHF or UHF because the impedance was between 20 and 40 ohms (depending on dielectric). People mistakenly thought the UHF (Uncle Harry Frankforther) connector was for Ultra High Frequency, just like they think the BNC means bayonet naval connector. Don't trust those people ;-) .

1022. Re: Variable Caps in Oil

Newsgroup: rec.radio.amateur.homebrew

From: w8jitom@aol.com
Message-ID: <3kmqb3$dl@newsbf02.news.aol.com>
Source record: 113820

I wonder if I should have said,

"While some oils are better than others, they are much worse than air or a vacuum for the application mentioned.

In a normal bypass or blocking function, if current levels are reasonable, an oil cap will probably function satisfactorily. A low frequency power supply filter is an example of this application.

But if the cap is part of a resonant circuit with high circulating currents, an oil filled cap will offer less than satisfactory performance. The additional dielectric loss will cause heat dissipation problems, drifting, and reduced efficiency. Sealing the oil in the capacitor will be a cost nightmare for anyone trying to save the 100 dollar cost of a surplus vacuum cap.

Let me give two practical examples I have seen. In a small three foot loop antenna on 15 MHz, the radiation efficiency dropped from 42% to 23% when teflon sheets were placed between the plates of the tuning capacitor. The capacitor also drifted severly from the dielectric heating. Yet I'm sure we can debate how wonderful teflon is!

Ceramic also poses a problem when subjected to the stress in a tank circuit. The large ceramic 850 style caps heat severely and drift at the current levels found in typical 800 watt amplifier tank circuits.

So, if you find the unknown "good" oil source (that has a better dissipation factor and temperature stability than ceramic or teflon) and if you can seal the stuff in your variable, you will have an ok oil filled tuning cap. "

Hmmmmmm, come to think of it, I stand by my original statement for this application. Oil sucks, use air or a vacuum ;-) .

Hello,
I just picked up an old Motorola PT400 transportable FM
RadioTelephone on 158 Mhz. I'm wondering if anyone knows where to get
documentation on this unit? How to convert it to two meters? Any
accessories available?

The full model number is: P43DEN3100BM

Please help!
Thanks!

Prefer Email....

Chris

1027. Ten Tec kits ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-21 18:01:00 UTC
From: seront@seism1.ess.sunysb.edu

I've read somewhere that ten tec is also making kits.
Does someone know something about that?
I am also interseted by their address; phone, fax #.
Thanks by advance.

Bernard, KB2TGH

Err: This notation is *very* common here in Europe!

>The letter is located where a decimal point would go,
>and indicates what the units are. In your examples, 2p2 would be 2.2 pF,
>2u2 would be 2.2 micro Farads and n39 would be 0.39 nF (which equals 390
>pF). Resistors listed as 3k3 would be 3.3 k Ohms, 4k7 would be 4.7 k Ohms
>and 5k6 would be 5.6 k Ohms.

Exactly, that's the way it is. With this notation you can recognise even on a
very bad copy of a schematic (where dots wouldn't show up) which values to use.

>I would guess that 470R was 470.0 Ohms, and it might be used when a more
>precise value was needed. There is certainly no need to add the ".0",for
>a 5 or 10 percent part!

No, the R is added to depict the unit. Simple 470 could be mixed up with 4.70
or 47.0 on bad copies (see above).

>As far as "which cap to use", I think the 2p2 is exactly the same
>capacitor as the 2.2 pF, et cetera.

Well I think this question was ment as "What type of cap to use?". The answer
is a bit ambivalent: That depends where it is located. You wouldn't try to use
electrolytics in HF/VHF circuitry in the signal path (but maybe for decoupling
VCC). And on the other side it would be hard to get a 100uF NPO ceramic cap :))
Common design rules apply.

1029. 2m beacon plans?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-21 18:41:57 UTC
From: djohnson@acpub.duke.edu
Message-ID: <3kn6ll$u7@news.duke.edu>
Source record: 113828

Hello all !

I am inquiring for a friend, Titus, KD4WQT, who does not have net access
at this time. He wants to know about 2m beacons, mainly as an aid to
studying propagation. Can anyone direct me to some source(s) of info
on construction of 2m beacon transmitters, and/or operation of same?

My friend has had little experience building circuits, so simple
circuits for homebrew, or even kits, might be the way to go. I don't
even know much about the existence or usefulness of 2m beacons, but
I suggested that he might check the ARRL Repeater Directory as a start.
Any other suggestions?

Thanks for your time and concern in this matter. Please send replies
to my email address (in header and signature lines).

Sincerely,

Dave Johnson

: >amp for this?

Yeah, from that power level, I would suggest a 2n5109 style,
broadband (transformer coupled) stage.... for fm, that'll take you
easily to a decent fraction of a watt. Above that level, I'm not sure
what to tell you.... Motorola just discontinued a bunch of their
bipolar RF transistors... I had a 15 watt transmitter designed for a
transverter that I've been working on, but they've taken my parts
away! (wah!). It looks like I'll be using TMOS fets to generate the
power (first a couple watts, then a stage to take it up to ten or 15).
I want FETS because I need the linearity, but you ought to be able to
find some suitable FM (class-C) transistors for FM lowband stuff.

One of the transistors they discontinued was the MRF-476,
which is a "CB" style final output transistor. If you can find a
replacement part, that ought to be good for 3-5 watts of FM at 50 MHz.

Good luck, let me know how you make out... I'm
interested in 6m too (that's why I'm making a transverter... for FM
use and SSB). I also think I have a pair of those radios... if I
could ever find them :)

1031. RF/Wireless Jobs/Companies

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-21 19:40:45 UTC
From: lascal@magritte.its.rpi.edu
Message-ID: <3kna3t$9cr@usenet.rpi.edu>
Source record: 113830

Hello,
This may border on the inappropriate, but what the hell.

I know several people, myself at the forefront, who are interested in getting jobs in the wireless/rf engineering sector (yes, we're EE's here at RPI). Does anybody out there have anything to say about where we should look? (I've seen plenty of people posting to this newsgroup... from such companies) I'm looking work doing circuit design, however I know several people interested in system engineering.

Most of us have sent out resume's.... and we've snagged a few interviews, but Human Resources departments often get in the way of seeing what we have to offer (motivation, practical experience with RF/Microwave design/evaluation/behaviour). Surprisingly I've run into companies that seem to think that enthusiasm for ham radio is a BAD thing. It seems to be a trend that good RF engineers are hard to come by (and seem to be getting older....). Clearly, higher education can only do so much to "create" a good RF engineer... because there are so many practical issues that one has to have an understanding of alongside the "theory".

I would assume that there have to be tons of companies looking for people during this boom we're experiencing.

Thanks for any help, and once again I apologize if anyone finds this inappropriate. Any flames should be directed to lascal@rpi.edu, and any good information or advice could be either posted or mailed.

Mike,

This is a very simple thing to do. Just connect the audio
of your FM RX to a SSB TX. If you plan however to convert a
FM TX to a SSB TX, you will find that there is no way
than building the SSB rig essentially from scratch.

Sorry for not having a positive answer, Moritz DL5UH

1033. Digital Semiconductor junction signature analyser

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-21 22:03:43 UTC
From: ed@fore.com
Message-ID: <3knifv$ej3@shell.fore.com>
Source record: 113832

I've been tinkering with this idea for about 5 years now, time to
share this toy with others. It is primarily used to diagnose bad parts
in broken electronic devices. It also can be used as an educational aid
in learning electronics, or a general purpose experimenter control and
computer measurement system.

I have designed and built a digital component tester that hooks up to
a dos computer to display and store/retrieve the signatures. The unit is about
the size of a modem. Has a built in microprocessor and a>d and d>a conversion,
opto-isolated rs232 serial port, generates a -12/+12 volt current limited ac
signal to sample the device under test, and a -/+12v base bias generator
for testing transistors and fets. Software has graphically aided learn and
compare modes. Tests diodes, zeners, caps, resistors, inductors, input &
output junctions of digital and analog IC chips, leds, opto devices, transistors,
fets, gate triggered devices...and it has other uses too.
I call it DIG-SIG.

Does this sound like something interesting that you would want?
Would you want it in kit form? Would you like to see it as a magazine
construction article (Radio-Electronics or Ham magazine?)

If so let me know. Email Ed@fore.com

I have done a previous RE construction article on a simple circuit with
some basic VCR theory called VCR Head Amp Tester. (Radio Electronics Jan 1991)

At this time, this is slightly more than vaporware, I have built 4 prototypes
so far, and am preparing to have the pcb commercially mfged. Est price would
be around $175 for the kit. Would this be useful to you?

Your opinions are requested. Email to Ed@fore.com

Any one intrested in an ICOM 02at Handheld.

Includes :
IC02AT
2 Batteries(one quick charge,one normal)
Base charger BC-35
ICOM hand mike

The IC02AT will transmit at both 5W and 500mW with the 12V battery
and 3W and 500mW with the 8V battery (I have one of each).

All 16 DTMF keypad, 10 Memories, Memory Scan, Sub-audible tones.

The cost is $300 collectivily but feel free to make me an offer an any
part of this package or the whole thing. It's going to go before May 18!

Any questions can be directed to my email address at :

mslatter@leo.crc.monroecc.edu

1037. attenuating 100w xcvr RF

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-22 00:55:46 UTC
From: kaul@netcom.com
Message-ID: <kaulD5tH8z.4Dy@netcom.com>
Source record: 113836

I've noticed a few people asking about 'how to build attenuators' to
reduce the power of 100 W rigs. SOMETIMES YOU CAN REDUCE THE POWER
WITHOUT AN ATTENUATOR! If your rig has an ALC input (usually it is a
jack, often RCA-or phono-type on the rear chassis), you can often force a
power reduction by introducing a negative voltage to the center pin.
I've built a small box which works with both my Kenwood and my Icom.
It is quite simple:

I use a 1.5V AA battery, and wired + to ground. The - terminal goes to one
end of a 25K pot, and the wiper of the pot goes to the center conducter
of a piece of shielded wire (the + side of battery connects to the shield
of the shielded wire). It should look something like this:

```
----------------------/\/\/\/\/\/\
| ^
| |
|- |_____________________________ to ALC
_____ ----------------
------- (battery) |
|+ -----
----- \ \ \ (gnd)
\ \ \ (ground) .
```

TUNE: load xmtr for minimum power output and gradually
adjust POT for desired power levels. Suggest you feed
this into a dummy load while making adjustments.

My Icom 725 literally will reduce to milliwatt levels (far lower power
than my ability to measure it!)

Warning, reduce power before connecting to transverter, otherwise your
transverter may be damaged by excess RF!

Good luck. de Alan, W6RCL

Various folklore tales abound about the naming convention used for BNC's.
I think so many stories have been told that it is difficult to separate
truth from fiction. Anyway, here goes my $.02.....

The story as told to me was that back during WWII, the Navy needed a
good connection that was resistant to moisture, provided decent RF
connection for their equipment, etc. It was called an NC for Navy
Connector. Later, a smaller non-threaded version was created and
dubbed the Bayonet Navy Connector, (or Baby Navy Connector) or BNC.
Not sure if that's for real, but it makes for a good story.

< Above Commentary edited>

I think that you are looking at the proverbial chicken and egg issue. Many of the opportunities in the wireless industry are based on shipping products fast. Many of the companies are on the small side, where they cannot afford the year learning curve that a freshout RF engineer will take. Thus, the growth in demand for experienced engineers, and the dearth of opportunities for freshouts.

Based upon my experience with the hiring of freshouts, I would have to say that a suprising amount is due to having your resume in the right place at the right time. I suspect that your best chance is to target the large companies playing in the wireless PCS market, where you can come in as a blank freshout, and be trained in the company way, or to look at the smaller companies, where you might be the only RF guy there, and so would have to do everything.

I'm not suprised that some companies see a ham license as a negative thing. Unless you have published articles in the ham technical journals, home-brewed a receiver < not an app note special >, or otherwise proved your technical chops in the ham radio venue, a license is irrelevant. Working DX, doing disaster relief, etc. isn't important for a RF engineer. What is important is technical ability and motivation. In addition, some of the hams that I have worked with have spent 90% of their time working on side projects, the ham club repeater, etc, etc, etc. That, in combination with

their being ignorant blowhards, makes a ham license a perceived negative. The thought would be " how much time is this joker going to spend working on a 0.2 dB NF preamp for his EME setup, rather than working on what he should be doing."

Just my personal comment. Take with a grain of salt, please.

The Heath Company still exists, but they are no longer making "HeathKits". They only sell assembled units, and have shifted their focus more toward teaching courses in electronics, computers, and such.

They still have replacement parts available for kits, at least for some of their later kits. I was able to get some transformers for a Weather Computer a couple of months ago.

INFORMATION ON "the Bell Jar"
Vacuum Technique and Related Topics
for the Amateur Investigator
ISSN 1071-4219

The Complete Newsletter and Journal
for the Vacuum Experimenter

Access to moderately good vacuum apparatus can open up a whole new
dimension to the amateur. However, practical information has not been
easy to come by.

In the 1950's and 1960's there was some level of discourse on simple
simple vacuum apparatus. For those who remember, two good examples
were C.L. Stong's Amateur Scientist column in the Scientific American
and the amateur oriented pumps, kits and plans once offered by the
firm of Morris & Lee of Buffalo, NY. Between the two, an impressive
array of apparatus emerged from the efforts of ambitious basement
experimenters. There were a variety of gas lasers, x-ray tubes,
potential drop accelerators, mass spectrometers, simple & compound
electron microscopes and high altitude chambers, to name a few. All of
these were cobbled together with converted refrigeration compressors,
single stage diffusion pumps, copper & glass tubing, wax and a lot of
ingenuity. The staying power of these endeavors is evidenced by the
continued recycling of plans (often in the form of poor imitations)
for a number of the vacuum related projects in Stong's columns.

In the intervening years there has been an almost complete lapse in
the availability of up-to-date information on vacuum technique and

apparatus specifically targeted toward the amateur, educator, or professional who likes to tinker.

"the Bell Jar" was created at the start of 1992 to bring together those experimenters who have an established interest in vacuum as well as to promote vacuum technique as an interesting and challenging hobby.

Nearly three years later, the readership numbers in the hundreds and contributors range from true amateurs to professionals with established credentials in the field. This diversity has made for a lively publication and has resulted in favorable comments from the professional community (e.g. "There's Life in this Bell Jar" in the Newsletter of the American Vacuum Society, May/June 1994).

The following outlines the article content by annual volume:

1992-Vacuum basics, elements of an amateur's system, conversion of refrigeration and auto a/c compressors to vacuum service, a discharge tube gauge, magnetically driven plasma accelerators demonstrated with a rail gun, history of vacuum units, a mini system for fabricating graded density optical filters, a universal thermocouple gauge controller.

1993-Plasma apparatus developed from microwave ovens, vacuum system operation, a coaxial plasma gun, synthesizing fullerenes, easy fabrication of glass to metal seals, reconfigurable vacuum chambers standard glassware components, a baffle chiller made from a room dehumidifier, exploding wires, units of outgassing, Magdeburg hemispheres made from plastic pipe fittings, production of low temperatures, a homebuilt diffusion pump, principle of the pseudospark electron beam source.

1994-Experiments with x-rays produced by receiving tubes, building a multiplate chamber pseudospark electron beam source, a kit of components for conducting gaseous discharge and electron beam experiments, building a simple cathode ray tube, a De Forest style audion triode, electron optics kits from the 50's and 60's, a simple chilled baffle for small diffusion pumps, an amateur's homemade transmission electron microscope, compression fittings from the sink drain, simple electrical feedthroughs, amateurs rebuild a large vacuum coater for telescope mirror making, original thought experiments in vacuum, a 250 kV impulse transformer, a cheap oil mist filter, simple ways of making electron and ion optics, a radio using the homemade vacuum triode, cleaning procedures for epoxy bonding.

Plans for 1995 (and probably beyond) include simple apparatus for classroom use, simple Pirani and Penning gauges, a windowed vacuum tube for transmitting electron beams into the air, ideas for original research, a shock tube for simulating micrometeorite impacts, low and high power pulsed x-ray sources (the Mather device, micro z-pinch, etc.), a crossed-field tube capable of initiating nuclear reactions, a 1-1/2" diffusion pump, topics in ultra-high vacuum, novel high voltage pulse

and dc power supplies, vacuum coating, demonstrating the multipactor (electron multiplication) effect, plasma immersion implantation the easy way.

Regular features include free classifieds, readers' commentary, items of interest from the professional literature, notes on suppliers of vacuum components and scientific apparatus.

Subscriptions to "the Bell Jar" are on a calendar year basis with issues mailed in January, April, July and October. Subscription orders received after November 1 begin with the first issue of the following year unless otherwise specified. Each issue contains an average of 16 pages of well packed and neatly composed content with no commercial advertising. Back volumes are always available. Prices, including first class or air mail postage, are:

1995 $20 (US addresses), $23 (Canada, Mexico), $29 (elsewhere)
1994 $20 (US addresses), $23 (Canada, Mexico), $29 (elsewhere)
1993 $20 (US addresses), $23 (Canada, Mexico), $29 (elsewhere)
1992 $15 (US addresses), $18 (Canada, Mexico), $24 (elsewhere)

Electronic Version

As an adjunct to the hardcopy publication, a truncated ascii format version is being produced on an irregular basis. Comprised of material extracted from "the Bell Jar", this version appears as a posting on several Usenet newsgroups. Individuals may also request to be placed on the distribution list by sending email to the editor.

I don't think you will learn very much from constructing a kit, if you
are starting from scratch. I'd build a simple "crystal" Rx to start with,
and work your way up from that. Add a simple AF amplifier, then an RF
amplifier. Then use the resultant TRF Rx as the IF amplifier and AF
stage for a superhet, by adding a mixer and local oscillator. This
type of Rx will only be suitable for AM, of course. You could substitute
a regenerative detector for the diode detector and alter the frequency
coverage, enabling you to listen to CW and SSB amateur transmissions.
This was basically how I started 30 years ago.

Alternatively, a simple direct-conversion Rx, would enable you to listen
to amateur transmissions straight away, although you probably won't learn
as much.

The ARRL Handbook which you should be able to find in any good bookshop
is full of the basic "building blocks" for the types of receiver mentioned
above. Your local amateur radio club should also be able to provide you
with lots of advice and assistance.

Is this a solar flux monitor you are building (10.7 cm) or are you also
interested in other sources in the sky ?

If you are building some kind of radiometer you should use as large
bandwidths and long integration times as possible for best result.
The sensivity is proportional to the (square root ?) of the
bandwidth * integration time product. Using some narrowband 2 m equipment
as the IF-stages would require very long integration times to get any
usable sensivity. Only if the spectral line is narrower than +/- 8 kHz,
it makes sense to use the IF-strip of a narrow band FM-receiver.
At 2800 MHz, +/- 8 kHz doppler shift corresponds to velocities below
+/- 1 km/s and thus most spectral lines of any stellar sources are much
wider than this.

To compensate for the gain drift during long integration times, you
must be able to compare your receved signal with a known noise source,
such as an antenna relay switching a few times a second between your
antenna and a 300 K noise source (50 ohm dummy load). Alternatively
a reference antenna pointing to a "cold" part of the sky can be used
as a noise reference.

> Is an interdigital filter a converter?

An interdigital filter is just a group of resonator sections connected
together with the stray fields of the adjacent resonator sections.
Some designs have a built in mixing diode at the end of the filter and
in this case we can talk about an interdigital converter.

1050. ### Help wanted: Construction of a Gel cell charger...

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-22 16:50:30 UTC
From: s2202629@np.ac.sg
Message-ID: <3kpkgm$kgm@nova.np.ac.sg>
Source record: 113848
Cross-posted to: sci.electronics,rec.radio.amateur.homebrew

I've recently acquired a 12V 10Ah sealed lead acid battery, and am interested in constructing a charger for it.

I am looking into the cct in the "ARRL Handbook for Radio Amateurs (1994)", but have got several questions about it.

Anyone out there who has built one of these beasts, could you perhaps help answer a few questions I have?

Basically, I'd like to know if I wish to step -up- the bulk charge current, do I only need to change Rs? With a max rate of C/4, a 10Ah battery I presume can be rigged up with 2.5A maxmimum.

I'm interested in rigging up the charger with a bulk current of either 1A or 2A, depending. If I set it up to 2A, would it mean it would take 5h for a charge cycle?

Finally, is the TIP42 able to drive a 2A bulk charge? In the article, there is a "A note of caution: The o/p drive of the '3906 is limited to 25mA. This may not be enough Q1 drive for high bulk currents. If so, choose a more sensitive current amplifier to take the place of Q1".

Is 2A considered a "high bulk current", if so, what would be a recommended replacement for Q1? Do I need to change any other components?

I'd also like to know what would the difference be if I were to use a bulk charge of 0.5A, and 2A, would it affect battery performance/life?

I would appericiate some help on this, please email me. Thank you.

1053. FM^2 and TTY Signals

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-22 17:58:05 UTC
From: kaiserpa@mwk.com
Message-ID: <1995Mar22.115805.2766@mwk.com>
Source record: 113851

What is FM^2? How is it modulated/demodulated?

Another question I hope someone can help me on is the Hamcomm RTTY baudot mode. I have a friend who is deaf and he wanted a way to transmit TTY baudot 45.5 baud over the phone line using his computer. I though the Hamcomm program and circuit would work perfectly so I built the circuit and recorded some of the TTY signal to play back to the Hamcomm program. I got garbage. Everything is setup correctly but the characters are different. Does anyone know if the deaf TTY baudot uses a different character set than the Hamcomm program or am I just missing something.

Thanks,

Patrick

It stands for itty Bitty N Connector, hi.
Actually I think it stands for bayonet N Connector. Where N is just
a type of connector that Amphenol (sp?) came out with.

>: I have heard two versions... "baby N connector" and "bayonet N
>: connector". I can not testifiy to the veracity of either of these, but
>: suspect the bayonet version may be correct.
>: Bob Liesenfeld WB0POQ

And once again:

BNC - Bayonet Neill-Concelman
TNC - Threaded Neill-Concelman
N - Neill
C - Concelman

Neill & Concelman were the engineers who developed the whole
family of connectors (BNC, TNC, N, C) and thus they are named after
the developers (BTW, "Concelman" may not be correctly spelled).

Any definition ending in "connector" (such as "baby N connector")
would make the term "BNC connector" redundant, so I doubt if any
engineer in his right mind would invent a connector which used the
word "connector" as part of the acronym. Common usage for all
standard connectors attaches the word "connector" to the abbreviation
(BNC connector, UHF connector, SMA connector, D-connector, N connector,
RCA (or phono) connector, etc.).

kaiserpa@mwk.com wrote:
: What is FM^2? How is it modulated/demodulated?

"FM Squared" --trademark Wegener Corporation is really just an extension of the audio subcarrier concept as used in "audio above video" in satellite video applications.

Usually, audio subcarriers (which are frequency modulated) are summed together with baseband video, and this whole soup is used to frequency modulate the satellite carrier.

In FM^2, there is no video. You just sum a bunch of previously modulated FM subcarriers, and then use them to FM modulate the satellite carrier. Really, the absense of video and the resultant room for more subcarriers is the main distinguishing feature of FM^2. Often, the modulation index is set such that the optimum receiver IF bandwidth is not 36 or 25 MHz, as in normal video receivers, but more like 14 MHz or so, so smaller antennas can be employed (less noise bandwidth). Experimental systems have been proposed with IF bandwidths as low as 7 or 8 MHz.

The FM^2 carriers on an FM^2 transponder will usually be a mixture of audio and data carriers. Usually, but not always, the audio will be companded using the Wegener Panda I (tm) companding system. I think regular 2:1 companding is also common.

I think the two transponder vendors supporting the FM^2 space segment are United Video and Microspace.

I believe the above information to be at least 90% accurate, but 100% accuracy is not guarenteed!

I vote for the story from two people who mentioned the engineers by the names of Neill and Concelman. The BNC came from a collaboration between them, and was called the Bayonet Neill-Concelman, or BNC. This info (and a little more about the N and C connectors) was on page 38 of the October 1989 issue of QST, in the Technical Correspondence section, titled "Coaxial-Connector Alphabet Soup", submitted by Kent Britain, WA5VJB. An editorial comment below the letter said that the information originally appeared in the May 1985 issue of QEX magazine, another ARRL publication. (I can't vouch for the authenticity of this, since I wasn't even born when these connectors were designed, but at least this info is in print and it can be verified that I am accurately reporting on what I saw in print :-) .) 73 DE WA8MCQ

Hello --
I have been a ham for about 2 years and have kept entirely to U/VHF on my Kenwood handheld. I have had a blast with it but am now interested in some other things.

First, I have recently gotten into homebrew stuff and am having a lot of fun with that. Second, I have a friend who is moving to eastern North Carolina (I live in Nashville, TN), and we would like to stay in touch by radio.
I am interested in finding a transceiver kit suitable for this purpose.

If anyone can give me some advice on one or more of the following matters, I'd very much appreciate it:

1. We want our communications to be as reliable as can be expected (Nashville <--> eastern North Carolina). What wavelength is likely to give the most reliable results at a distance of approximately 600 miles? 40m? 80m? 160m?

2. How much power will I need to use? (I know this depends on many factors.)

3. Is it possible to have an antenna appropriate for 40m, 80m, or 160m that is effective, but isn't as long as a football field? I live in an apartment building, on the top floor.

4. I would like to build the stuff myself (a kit... I'm not yet to the point of doing it from scratch!). Can anyone recommend a maufacturer of 40m, 80m, or 160m transceiver kits?

That's it. *Whew* I know this is quite a lot to ask. Even if you can supply info about just one of the questions, it would be extremely helpful.

Thank you.

You can bet your shirt, that PC transformers will not survive anything they have not been designed for. (May be you can improve insulation or put together better high frequency transformers, sounds a good idea though).

Still, the switching device in a PC power supply is intended to swith the 220 V, and it seems stil a big problem to me to switch 10 or so A at 12 V without too big losses. (correct me if I am wrong)

I was wondering if anyone had any schematics for the biginner trying to learn about ham radio. I just bought the 96 ARRL handbook and there are few "simple" schematics. I was wondering if anyone had scans of some and could share them. What I am looking for is say a simple, least number of components, receiver and CW xmtr.

Erik

I'm emailing you a schematic of a modem that can support almost any baud
rate with appropriate component changes (a couple of capacitors and/or
resistors). The BAYCOM SOFTWARE will not support such baud rates but
this modem will.

This works, however, it is not always desirable. When you throttle these
PAs down to the milliwatt level, the intrinsic noise floor of the
amplifier can nearly equal the desired signal, so you're transverting
as much noise as signal.

A 30 db coupler in the line to a dummy load is a good alternative
way to get a low power signal for the transverter.

>(Nashville <--> eastern North Carolina). What wavelength is likely to
>give the most reliable results at a distance of approximately 600 miles?
>40m? 80m? 160m?

80m is your best bet in the evening, 160m as the night goes on, but
summertime static can make both bands miserable. They're much better
in winter. 40m is the only choice in daylight. At night it lengthens
out too much, and the international broadcasters will come booming
in to aggrevate the already high interference level.

>2. How much power will I need to use? (I know this depends on many factors.)

Yes it does. In summer, on 80m voice, you may need the legal limit at
times, though 100 watts will normally be sufficient. Using CW or data
modes, lower power will generally suffice. 50 watts should do the job
even on some of the more obnoxious summer evenings. You'll have to pick
and choose your times carefully to make it with 5 watts or less.

>3. Is it possible to have an antenna appropriate for 40m, 80m, or 160m
>that is effective, but isn't as long as a football field? I live in an
>apartment building, on the top floor.

Well, you can do it on 40 and 80, but 160 meter antennas start to
reach out to football field length. :-)

For that path, you want a fairly high angle radiator. A low dipole
will work well while a vertical is the wrong thing to use. You can
end load a 40 meter dipole to make it work on 80 as well, following
the principle of the Lattin antenna. That'll be a 66 footer which
you can probably hang low over the apartment house roof.

>4. I would like to build the stuff myself (a kit... I'm not yet to the
>point of doing it from scratch!). Can anyone recommend a maufacturer of
>40m, 80m, or 160m transceiver kits?

Well, there are two or three makers of small low power CW kits. I don't
know of anyone still offering SSB rigs as kits since Heathkit's demise,
but there may be one or two. QRP isn't likely to be the way to go to
keep a schedule on these bands, however. I'd suggest you want something
in the 100 watt class. Any of the older amateur rigs will do for this job,
and you can modify some of them to your heart's content, and probably
save money over a kit too.

Many of the older rigs can stand improvement to their audio amplifiers to eliminate hum and better shape the audio. They can stand improvements to their receiver front ends to improve overload response. And they can stand better IF filtering. Each of those steps can be a separate project that can keep you interested for several weeks to months. You're likely to learn more modifying these old radios than you will by building a kit. And best of all, you'll start with something you know worked before you got into it. That can be a major help to the neophyte designer/builder.

Something like a TS-520 or older Ten-Tec would make a good starting point. Old Drakes are good enough you probably wouldn't want to tinker with them. Best of all, you may find an older Heathkit with manuals. Any of those should be available for under $300, perhaps way under $300 if they're a bit sick.

I KNOW it is only a pet peeve of mine... And I really shouldn't bother sucking up bandwith with this. BUT... In this question and many others offered here in good faith, so many people are willing to jump in with baseless suppositions or vague feelings. Why do they bother? I bet some readers here could dig up copies of the standards forms used to propose and grant acceptance to any connector that is commonly accepted and rated by an international organization. This would be the undisputed source of the common nomenclature for anything. Now, maybe the official standards name of the BNC is some numerical string, and the string "BNC" was adopted from common public usage. I don't know. But I would love to see someone post a reference here from official proposals or standards documentation.

Beyond this, I am sure that commercial and nationalistic interest would compell some leaders to fabricate false meanings to common acronymns. For instance, if Bell Labs employees Neill and Councilman actually first designed and fabricated the "BNC" connector and Bell Labs submitted it for military and international acceptance under the name connector, "Bayonet, Neills, Councilman," and if the British navy adopted it for usage, I am sure some official stuffed shirts would think that the name should reflect something British. So, official word may have come down the line that the connector be known as the "British Naval Connector."

Whoa, I am frothing at the mouth and raving. I only wanted to ask
people who aren't sure about an answer to not bother replying. Please,
somebody shoot me...

Look at "W1FB's Design Notebook", "W1FB's QRP Notebook", "QRP Classics" and "Solid State Design for the Radio Amateur", all ARRL publications. The two Notebooks are probably closest to what you're looking for, but they're all good reading.

Chip-

According to the D. A. T. A. Transistor volume, your device is most likely a 2SK135, rated at 7 Amps/100 Watts, in a TO-3 Case, manufactured by Hitachi. The book didn't list a voltage rating, which might be the critical parameter for driving a relay coil.

Does the relay coil have a reverse-biased diode across it? Such a diode will reduce the induced voltage spike when the coil is turned off, although it will delay the relay opening.

The 3SK135 appears to be small, maybe a surface-mount package ("SOT"?), and is manufactured by NEC.

Hi,
I have posted this before...I don't know if anyone saw it...but I have the definition IN WRITING in the ARRL UHF/MICROWAVE EXPERIMENTER'S MANUAL right here in front of me. It has a whole section on connectors, beginning on page 5-17. "BNC" stands for "Bayonet-Neill-Concelman", "N" stands for "Neill", C stands for "Concelman", TNC stands for "Threaded Neil-Concelman". Also, OSM stands for "Omni-Spectra Miniature" and SMA stands for "Sub-Miniature type A".
The section of the book describes the connectors and why and when they are useful. Also has a lot of photographs.
I figure a textbook on this would be the definitive answer, as I haven't seen anyone else actually list a written source for the definitions of these terms.
...Where'd I put that British Naval Connector? :-)

73,
Zack W9SZ

1079. Need schematics for an FM transmitter and a receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-24 00:56:17 UTC
From: industry@texas.net
Message-ID: <3kt1lu$8pg_001@dialnet49.texas.net>
Source record: 113777

I need some schematics for an FM transmitter that is inexpensive, small and easy to build. I also need plans for a receiver with the same qualities. I'm transmitting DTMF tones and decoding them at the other end for a remote control. I need a 1/4 to 1/2 mile range. They can be fixed-frequency or whatever. Please email any suggestions or plans to <industry@texas.net>.
Also any FTP or WWW sites with plans/schematics on transmitters, receivers, and DTMF encoders/decoders would be appreciated. Thanks in advance...

1080. NEED HELP WITH REPEATER!!!

Newsgroup: rec.radio.amateur.homebrew

HELP!!!

I am putting up (hopefully) a "homebrew" 440 MHz repeater within the Milwaukee, WI area, serving a good chunk of the Southeastern Wisconsin area (esp. outlying Milwaukee Metro). I have a GE MASTER II, 8 channel, 40 watt 450-500 ranged mobile unit, WITH instructions and everything.

I want to place this thing in the amateur band. Now...

I understand that these radios can be modified to receive/transmit properly within the amateur spectrum, but am having problems finding any appropriate documentation regarding this equipment. Seeing how old it is, I have had quite a bit of difficulty within the Milwaukee Metro area finding anything to do with any form of amateur radio.

I NEED HELP!!! If anyone has information who currently has or can point/steer me in the right direction to someone who current has information regarding modifying the GE MASTER II, 8 channel mobile radios into a repeater, I would like to have an email address and/or telephone number along with the name and callsign of the individual.

I am retrofitting this equipment into an existing MOTOROLA MOCOM 440 MHz repeater that works, but the receive isn't too hot. I've heard that GE's equipment is far more adjustable and easier to work with than MOTOROLA's.

Any comments and/or help?

Again... I NEED SOME HELP FROM ANYONE ON THIS MATTER!!!

Please send email to this address: helix@solaria.mil.wi.us

Thanks and 73 de KC6ONL!

> companies that seem to think that enthusiasm for ham radio is a BAD
> thing.

That's too bad but that's THEIR loss. A Ham license alone is not the Holy Grail to a good job but can definitely help. The key is to demonstrate in the interview how ham radio ties into the job your interviewing for. Even something as apparently simple as curing a TVI/RFI problem your transmitter has caused demonstrates effectiveness at solving tough, "real world" problems.

daveb@gate.net (David Bengtson) wrote:

>take. Thus, the growth in demand for experienced engineers, and the dearth
>of opportunities for freshouts.

True.....but freshouts also give fresh life to tired, old organizations. I've learned allot by explaining (or trying too!!) theory and practice of design to a freshout. They are sharp, analytical and keep the old-timers on their toes with their "simple" questions.

>Based upon my experience with the hiring of freshouts, I would have to say
>that a suprising amount is due to having your resume in the right place at
>the right time.
Very, very true.

>I suspect that your best chance is to target the large companies playing
>in the wireless PCS market, where you can come in as a blank freshout,
>and be trained in the company way,
Be careful not to get pigeon-holed....
"Joe, learn PLL's 'cause you'll be doing synthesizers for the rest of your life...."

>or to look at the smaller companies, where you might be the only
>RF guy there, and so would have to do everything.
Can't recommend it.....you'll want a good mentor. You can VERY
quickly get in VERY deep in RF design. A good mentor can help steer
you clear of a disaster....and quickly help in getting you out of trouble.

I like small companies best.....you get to do a bit of everything.
Systems engineering, marketing, design engineering, EMC testing.....
You get the whole enchilada!

>I'm not suprised that some companies see a ham license as a negative
thing.
>Unless you have published articles in the ham technical journals, home-
>brewed a receiver < not an app note special >, or otherwise proved your
>technical chops in the ham radio venue, a license is irrelevant.

Disagree completely......
Designing a receiver from an "app note special" is a pretty dam good thing

for a freshout to have done. No decent engineer EVERY starts a design
from
scratch. That's pure stupidity. App notes are written by very bright
people
who's purpose is to get a designer started off on the right foot when
working
with their part. They are not meant to be the last word on receiver
design,
but they are a good start. Anyway, you'll find that copying an app note
for
a receiver design is just the beginning......debugging it will take a
newbie
some time and that time is spent learning! Nothing wrong with that.

>Working DX, doing disaster relief, etc. isn't important for a RF
engineer.
Working DX quickly teaches you something......."It's the Antenna, stupid."

>What is important is technical ability and motivation.
Agree 100%. No substitute.

>In addition,
>some of the hams that I have worked with have spent 90% of their time
>working on side projects, the ham club repeater, etc., etc., etc. That,
in

How about all those "hackers" masquerading as engineers...
They waste allot of time playing with their computers, optimizing their
SVGA drivers, windows configuration files, etc. There will always be
engineers
who can't effectively manage their time, ham license or not!

>combination with their being ignorant blowhards, makes a ham license a
>perceived negative.
I won't even touch this one!

>The thought would be " how much time is this joker going to spend working

>on a 0.2 dB NF preamp for his EME setup, rather than working on what he
>should be doing."

>Just my personal comment. Take with a grain of salt, please.
>Dave Bengtson

I understand and I did. Now for a few more of mine.

New grad hams are in a terrific position to understand the WHOLE system.....not just what the optimum bias point for a low-noise MOSFET is. If they have done packet, satellite, SSTV or anyone of a dozen other modes they are WAY ahead of the crowd. How many RF designers understand what TCP/IP, X.25, or a TNC is? Not many.

Any ham who has poked inside a modern dual-band HT can learn something about the ART of high density, low cost RF product engineering.

You got to be able to use your ham experience to your advantage and demonstrate to prospective employers that your ahead of the game.

Just my two cents!

Good luck,

Bob Masucci

Source record: 113782

Hello,
Have any of you out there made your own board for the KK7B
no-tune 903-MHz transverter? (July 1991 QST.)
I requested and received the template for the board from ARRL and
copied the pattern onto Kodalith and then onto G-10 board. This is my
normal practice for making PC boards. The board appears to be an exact
replica of the template pattern.
For some reason, I cannot get the multiplier chain on the
oscillator section to put out any RF at 759 MHz. I have RF at 94.875 MHz
going into the multiplier/filter, and measured it at about 8 dBm. But no
power out of the filter/amplifier chain.
I don't have access to a spectrum analyzer or a receiver for 759
MHz, but do have a dBm power meter and frequency counter. Both perform
well up to 1296 MHz.
I thought I had a bad MMIC, even though the bias on all the
MMIC's is correct, so I swapped them all out. Still no mixer RF. Then I
swapped out the multiplier diode and chip caps; still no 759 MHz RF.
I tried the trick of replacing the Xtal with a 47-ohm resistor
and tuning the trimmer cap over a wide range of freqs, thinking maybe
some of the striplines were marginally tuned to the freq I needed...still
mo RF out.
I have made 4 540-580 MHz LO boards and 2 2160-2320 MHz
multipliers from the same sheet of G-10 and they all perform perfectly
over the entire frequency range. (See July 1989 QST.) I used the same
procedure to copy those PC patterns from the magazine article and make those
boards.
So this problem has me totally baffled! Any suggestions? Has
anyone else run into this problem? I'd like to get it going before the
June VHF QSO party!

1087. Homebrew tubes

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-24 15:55:26 UTC
From: dcadd@luc.ac.BE
Message-ID: <9503241555.AA03713@alpha>
Source record: 113785

Greetings from a pleasantly warm Diepenbeek in N.E. Belgium!

Bob Liesenfeld wrote concerning homebrew bottles. The degree of vacuum you need is really dependent on getting the electron mobility high enough. Putting it another way, if there's too much gas in the tube, you may end up with a thyratron instead of a triode! Typically, the vacuum needed is of the order of 1 x 10 ^(-6) mm of mercury. This is achievable with a diffusion pump, years ago the manufacturers used mercury diffusion pumps, but the same degree of vacuum can be obtained with oil diff pumps. Unfortunately, these pumps can't pump down from atmospheric pressure, and they need a 'backing pump' usually a rotary type which can reduce the pressure to about 1 x 10 ^(-2) mm of mercury before the diff pump takes over. To buy both types new is very expensive, but I've occasionally seen second hand ones offered by a variety of scrap/junk dealers. At a pinch (what an awful pun!) you could use the compressor from an old fridge (contaminate the ozone layer with its current contents!) as the rotary backing pump - it may be good enough connected as a vac pump - then you need a second hand diff pump! Plus oil or mercury! Very messy.

The long-term reliability problem (and maybe not so long term) is due to the fact that the electrode structure gradually evolves adsorbed gases because of course in a valve the electrodes get warm/hot. In early valve manufacture I think they got around this by very lengthy pumping whilst running the tube. Later, the use of RF heating (i.e. stick the whole valve inside a QRO tank coil whilst pumping loads of RF into it) combined with pumping, to heat the electrodes to red heat whilst drawing off the gas was used, and additionally a 'getter' was employed inside the tube. This is the silvery layer frequently seen on the glass. A small blob of more-or-less exotic alloy, containing barium or magnesium, was heated again by RF induction, when most of the gas had been removed as above. This deposits a layer of metal on the envelope of the valve and because the surface of this metal is chemically very clean, and also is chemically very reactive (magnesium and barium will even combine with nitrogen under these conditions) most gas which evolves from the electrodes after the valve is sealed and during its working lifetime will be effectively grabbed by the getter. This obviously helps to prolong the valve life and also avoids poisoning of sensitive cathodes, e.g. the 'modern' oxide-coated cathode which runs at maybe 5-600 C. 'Soft' valves have become soft generally due to (1) a defective seal (2) excessive gas emission from the electrodes (3) a defective getter i.e. the surface is contaminated or overloaded. Pure tungsten cathodes, whilst having the disadvantage of comparitively low electron emission and needing to be heated to white heat, nevertheless have the advantage that they are virtually immune to poisoning. Until relatively recently, tungsten was still the cathode of choice in such applications as electron microscopes which are regularly exposed to the atmosphere. There are still specialist applications where it is used - and obviously it would be the easiest cathode for an amateur tube brewer to work with. Oxide coated cathodes use a mixture

of strontium and barium salts on a heater, which are chemically changed during tube evacuation/RF heating - a little tricky perhaps to replicate and worse, the heavy metal salts are toxic and probably not available to Joe Public.

A variety of metals have been used for grid and plate structures - molybdenum for plates springs readily to mind, try consulting old valve radio books e.g. Henney or Terman - packed with fascinating info.

Finally, (!) soda glass as used in beer bottles and much domestic glassware has the advantage that it softens at low temperature, but is very susceptible to stress accumulation and cracking - reworking it is generally not done. In the glassblower's shop, here at the Limburgs Universitair Centrum we use borosilicate glass (like Pyrex etc) which needs a much higher temperature to work it (gas/oxygen flame) but which is rather better behaved than soda glass and which tends to make better glass-to-metal seals, another subject in itself. For one-offs, where the price is not prohibitive, platinum wire makes an excellent gas-tight seal (but I can't see them using it for 6146s!)

Hope this answers a few questions!

This shows up as a thread on sci.electronics about twice a year.

There is a good summary of connector development history in the ARRL Microwave handbook.

The N and C are the initials of the developers, Neill and Concelman (sp?) who also developed the 'N' and the 'C' connectors.

BTW, TNC and BNC have the same electrical characteristics, but the TNC is mechanically much more stable. The BNC is popular simply because it is faster to connect/disconnect.

1090. Need Transistor Data

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-24 17:36:43 UTC
From: gjk@hogpc.ho.att.com
Message-ID: <D5yGx8.EAK@nntpa.cb.att.com>
Source record: 113788

I'm trying to fix an intermittent problem with my Kenwood TS-940s. Occasionally, the radio loses lock. I've isolated the problem to a circuit which has had some repair work. If I spray a particular transistor with "circuit cool" the radio jumps back into lock. The problem may just be a flakey solder joint resulting from troubleshooting the previous problem. But, since it's such a pain to get at the circuit board, I figured I might just want to replace the transistor. According to the Kenwood Service Manual, the part is a 2SC2787(L). I've tried looking at replacement lists at local parts distributors and haven't found a substitute (yet). I'm still looking for data on the transistor itself. I'd appreciate it if somebody could send me some data about this so I could figure out at substitute. I really don't want to order from Kenwood since this takes too much time (and money!).

Thanks,

Gerry,

The Japanese devices are in widespread use at hi-fi/video service companies. To deal with specs and substitutions, they often use a book which is published each year that identifies 2SA thru 2SD semiconductors. The cover of the book is part Japanese, part English, but all the specs for the devices inside are in English.

I think it's called the "Transistor Data Book", and the repair shops obtain it from two companies that I am aware of: MCM Electronics (near Chicago, I think) and CEI Electronics.

Sorry, I've been out of the biz for a number of years so I don't have more information. Hopefully this will be enough to help you track it down.

Well I for one am looking for an RF Sustaining engineer. I will give serious consideration to New GRads and Freshouts with Ham BAckgrounds If you can demonstrate that you've at least done some serious homebrewing at 150 MHZ or above. You also have to make a serious commitment to moving to Spokane WA. Also looking for Rf TEST and Quality types as well. HAm experience is neither a hindrance or a help just a different kind of experience. Appliance operators however need not apply. For further info send me a direct E-MAil inquiry.

Equal Opportunity Employer...etc etc.

Hi Zack... Hmmm...My first thought would be to check the multiplier
diode... It looks like you covered that one though. Make sure it is the
correct part or an equivalent.
You might also play around with the coils in the oscillator by spreading
or compressing then or even removing turns. I had trouble with this
even though I was getting the 90-odd Mhz out, I couldn't seem to get a
harmonic until I played with the coils right at the oscillator.
Otherwise, make sure your freq. counter is working :)
These may be obvious things that you've already covered but worth a try.
Let me know how you make out !

Source record: 113799

Looking for data format and programming information on the M56760
PLL I.C. Datasheets would be nice ! Also curious to know who the
manufacturer is (Mitsubishi ??)

My Kenwood TM-741 triband FM rig uses these PLL's in the band modules.
I'd like to design a "front panel" for these modules so that I can
use any one of them standalone (without the need for the TM-741
chassis). This would require an audio amp with volume control, a
squelch control, a mic input, a couple of regulators for the various
required DC voltages and a microcontroller to talk to the PLL and shift
registers as well as monitor the PTT line. I have a test bed all laid
out...just need to determine the format and data to be sent to the
PLL chip.

Thanks...Hugh VA3TO Toronto hduff@humnet.westonia.com

-=> Quoting Werner@acsu.buffalo.edu to All <=-
We>
We> I was wondering if anyone had any schematics for the biginner
trying
We> to learn about ham radio. I just bought the 96 ARRL handbook and
there
We> Erik

What I would do if I were you (and I have done this to an extent myself
seeing
as I am in your position as well, cept I know quite a lot about
electronics)
is I would pick up your ARRL handbook and read it. About three or four
times.
It may seem boring at first, but press on. I have learned a lot in
about three
weeks time. Don't worry about understanding all of the formulas and
math and
stuff at first (although if you can, it is a big plus). Just read and
get
a general idea from it. You gotta want to learn. If you don't, the
book will
be boring. Otherwise it is a great reading source (not the type of
book to
take to the beach, but if ya wanna learn radio and electronics, it is
probably
the best).

Hope I helped some, and anyone should feel free to comment on what I
say.

IMO, this is one of the best pieces of advice for any newcomer. I did
the same thing, many years ago, and the Handbook gradually became
the foundation for my understanding of RF and electronics. Information
in the Handbook was sufficient to allow me to pass the General and pick
up the 2nd Class 'Phone, both without study guides.

Source record: 113806

For the purposes of discussion, if you have something like an FM receiver chip, presumably you could extract the output of the IF before the limiter stage, and process for SSB. A project in a recent ARRL handbook uses an MC3362 in just that way for QRP HF receiver. But the problem i see is the VCO: if it's within a few KHz, that's fine for FM. But i think you need to come alot closer to make SSB work at all (at least without DSP hackery), not to mention sound plausible. Such a VCO may be relatively easy to make for HF, but you won't get that stability very easily at VHF/UHF.

The T2 phasing exciter described in a recent QST is also supposed to be able to generate FM as well as SSB [April 1993, p. 30], but i don't think that's what you had in mind. Probably none of this is, but it'll probably stir up discussion nonetheless and some of us may learn something... But previous posters are right, you're better off starting from scratch rather than trying to hack something up.

From: demerson@heineken.tuc.nrao.edu
Message-ID: <3l2pp8$lbh@solitaire.cv.nrao.edu>
Source record: 113807

About 25 years ago, I bought a small trimmer capacitor with a variable temperature coefficient. This was intended to be used to stabilize drifting VFOs, and was superb at this task. It think it was called a "tempatrimmer" and made by Oxley in the U.K., although I'm not sure of these facts.

Does anyone know if it's still possible to get such devices, in the U.K., U.S.A. or anywhere?

Thanks,

1108. Homebrew tubes

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-26 05:05:22 UTC
From: EUGENE.WELCOME@rook.wa.com
Message-ID: <5F441C8A@rook.wa.com>
Source record: 113808

Hi again Duncan: I caught another mis-conception about tubes on Fido and because of my nature I put my foot in mouth and typed away. I hope this conference is receptive to trivia from the past.

No one dares ask me the time. They will be able to build the clock by the time I am finished.

***> Yep, but there are also valves like 12AX7W etc. These are
***> commercial tubes with usualy a coating over the filament to give
***> them a longer life.

Actually a commercial grade tube has precise alignment of the elements with more element supports. Military spec's call for heavier glass envelopes along with the hours of on line testing or so called burn in testing. As far as the filament is concerned, extra coating is not applied to the filament. There however is a cathode placed over the pure tungsten filament wires that is oxide coated. This coating is made up of barium and strontium oxides. In commercial and military tubes this coating is tightly controlled for thickness, composition and hardness. The oxide eventually flakes off with time and with tight manufacturing controls, this can be predicted for reliability applications demanded of the tubes in combat or most unforseen hazards they hope the tubes can survive. Now of course, this is not required as much now, except the large special purpose tubes the military or what industry still use.

Some info about Tungsten Filaments. Pure tungsten was one of the first materials to be used as a thermionic surface.(electron emission) Tungsten operates at a temperature of about 4070 degrees F with an emission rating of 2.7 amperes per square inch of surface. The emission efficiency at this operating point is about 0.004 Amp per watt of heating power. As with all other thermionic emission materials, the characteristics vary greatly with small changes in operating temperature. A so-called "cold" tungsten filament at 3600 degrees F produces negligible emission. Tungsten has a great advantage over other materials in its physical strength and its ability to have an effective infinite emitting life.

Thoriated tungsten filaments was developed to improve emission efficiency. A small percentage of thorium oxide is mixed with tungsten and the material is then made into the necessary physical structure required for the tube's filament. Then this filament is heated to just below the melting point. A monoatomic layer of thorium oxide works to the surface and is converted to pure thorium. This allows the use of tungsten's stength and higher operating temperatures yet will allow the thorium to emit at the temperature that thorium normally melts.

The results are, lower filament temp. of about 3000 degrees F and has a very high emission value of 7.6 amperes per square inch of surface. It also has a higher efficency of about 0.070 Amp emission per watt of heating power. Take a 5U4GB full wave rectifier, it uses thoriated tungsten filaments and can handle a peak of 1 amp of current. Example. The filament is 5 V at 3 A = 15 Watts times 0.070 A = 1.05 peak amp. If it had only tungsten filaments then the following applies. Filament is 5 V at 3 A = 15 Watts times 0.004 A = 0.060 peak amp. Of course the plate structure would get excessivly hot at 1+ amps so a continuous rating of 0.275 amps output current.
Pure tungsten is used only in tubes that have the cathode element added over the filament structure as mentioned above. Since we use AC power to light our tubes instead of batteries of long ago, tubes would introduce AC hum into the system and that is what brought about the developement of the indirect heated cathode. Besides, this gave the designers more choices of electron emissive elements that can be heated indirectly and yet not require a voltage directly to make it glow. Yet allows huge amounts of current to flow. Tungsten filaments are in reality cathodes in a tube stucture so the added indirect heated cathode as mentioned above opened up better designed tubes at lower watts of heater supply. Take the cathode coated with barium and strontium oxides. The operating temperature is lowered to about 1560 degrees F. The emission current is 3 amps per square inch of cathode surface with an efficiency of the order of 0.3 A emission per watt of heater power. One of the last rectifier tubes developed for TV's The 5AR4. It had the same base connections as the 5U4GB but with an indirect heated cathode directly connected to one side of the filament, pin 8. In fact this tube can be used in place of the 5U4 tube if the DC tap (rectified AC) to the filament is from pin 8 only. The 5AR4 fil. V = 5 at 1.9 A = 9.5 watts yet can handle 1 amp peak current easily. Filament is 5 V at 1.9 A = 9.5 Watts times 0.300 A = 2.85 amp. The max current for the 5AR4 is 0.250 Amp due to the smaller overall structure size of the glass bulb and plate size. A much cooler tube. Also indirect heated cathodes lowered the manufacturing costs of tubes. More Watt per Buck or translated to todays prices. More Watt per Kilo-Buck. :(

Keep Vacuum tubes off the endangered spicies list! Use them.

Hi Duncan: Thanks for an excellent post. What I offer enhances what you said and to save space I didn't repeat any text of yours. I do recommend yours for reading. It gives insight to Valve making. I offer some facts from the past about gassy tubes. I show a correct statement and a common mis-quote and I follow it with what really takes place as I was taught. I will also reset all Tube references to Valves. :-) I have worked on enough European Xray Machines in my career to feel comfortable with either notation. I had posted this on Fido in 1994 as a responce to gassy tubes and repost it to enhance your excellent post. Now I have to find those recommended vacuum pumps. I need more 6146's.

****** Its been a long time now, but I have read that a Blue glow on
****** the envelope of the tube is OK, if you have a Blue glow in
****** between the elements you have a bad gassy tube.
****** Whoa! It can't be both "OK" and "bad!"

But it can be "gassy" and be quite harmless, such as surface gas glow inside the glass envelope. See detailed explanation later.
Gas inside the element structure is not desired unless this valve was designed as a regulator, gaseous rectifier or gaseous triode/thyratron or tetrode/thyratron.
-6 -8
The vacuum in a vacuum valve = 10 to 10 mm of mercury.

Any molecule of air or gas of any kind left inside a vacuum valve after it has been evacuated will interfere with the free movement of electrons from the cathode to the anode (or any other elements in the valve). The manufacturer exhausts mos all the gas by mechanical pumping and then seals the outer glass or metal envelope of the valve. Inside are all the elements of the valve plus a small piece of chemically active metal, such as magnesium, called a "GETTER". By magnetic induction, the elements and the getter are heated. The getter explodes and combines chemically with the molecules of gas that are released by heating of the metal elements, or that are still in the valve, depositing part of itself in combination with the gas molecules on the inside of the envelope. From the outside this deposit appears as either a mirror-like or darkened area. Getters can be made from other materials such as barium, barium berylliate, zirconium, phosphorus and various mixtures of these. Some getters are designed to continuously remove gas which in effect maintains vacuum during the operation of the valve. They call these "KEEPERS".
A high degree of vacuum is known as "HARD VACUUM". A vacuum valve which is gassy for any reason is known as "SOFT VACUUM". Valves become soft because of leaks through the glass or metal envelope at sealed

edges or because of unintentional overheating of the elements, which may liberate some of the gas molecules that are normally present in metals. Keep those plates orange or less in color.:) Not white hot.:(Soft vacuum valves usually show a faint purple or light blue haze with-in the elements. The intensity of this glow varies directly with the plate current flowing through the valve.
Some valves, when operated at high plate voltages, produce a blue glow where electrons strike the inner surface of the glass envelope. This does not indicate the presence of gas but is the conversion of electric energy into light energy as the electrons strike some of the getter molecules or actinic glass molecules on the inner surface of the glass envelope.
Effect of gas upon the valve neutralizes the control of the grid over the current flow and can destroy the valve in short order. Positive ions created continuously by collisions between gas atoms and free electrons neutralize the space-charge so that large currents may be drawn at low plate voltages. In addition, the space-charge neutralization effectively increases the thermal efficiency of the cathode. This is desirable for mercury vapor rectifiers or thyratrons but in vacuum valves this spells destruction of the valve. There would be no way to control the current as the grid would be ionized positive resulting in the valve acting as a gas diode. (The grid lost control.) Now that takes care of the small signal type valve amplifiers.
Take power valves. You can not use getters due to the higher operating temperatures of the plate structure. The heat would evaporate the getter totally and poison the valve by destroying the vacuum.
Certain metals have the property of absorbing gases when raised to a high temperature. Example Tantulum will absorb gases when very hot. This makes tantulum very desirable to use for making plates and grids in power valves. Zirconium is another useful metal in this regard. At 1400 degrees C it will absorb oxygen, nitrogen, carbon monoxide and carbon dioxide. This metal is used in special valve designs that are very hard to evacuate during manufacture.

Yep! But VHF contests are very different from HF contests. They don't take up much of the band, and if you live in fairly flat Illinois, are best done portable from hilltops! The pace is usually much slower, too. And most of the CW is 10 WPM or less.

All my VHF/UHF equipnemt is homebrew, too.

Try it, you may like it!

Hi Zack:

The company I work for manufactures microwave television
transmitters for 2.5 GHz. Before moving into marketing,
I was involved in component-level work with this equipment,
so I know how critical circuit components can be as you
approach these frequencies. I also know how necessary
an analyzer can be when things don't work properly.

I'm not familiar with the exact schematic you're using,
nor is it part of my library. Nevertheless, I will assume
that circuit techniques are generally the same as those
I've worked with in the past.

Just wondered if you know anyone who has built the equipment
from the magazine article successfully? If not, I'd sure
be tempted to analyze the dimensions of the striplines and such.
Multiplier circuits seem to be particularly critical in this
regard; sometimes, the smallest error can be sufficient to
totally inhibit all output.

What I'm getting at is that the print for the board might not
be to scale. It wouldn't be the first time a print shop
resized a graphic slightly to make it fit the page, and
stripline mistuning will show up long before component leads
no longer match the holes in the print.

Just a thought.

73,

Jack WB3U

Hi Gerry, The transistor can be replaced by Phillips/Sylvania ECG107 or the NEC replacement line NEC107 or RCA SK9229. I have had good results with the substitutions by these three vendors. Many wholesale electronic supply houses offer the cross references free. Just ask.

Anyone else had trouble getting Ocean State Elec to ship orders
in a reasonable period of time ? I'm quite disappointed with them,
told them so after they "blew it" on an order and then they
did it again. Doubt that I'll bother with them, which is a shame
as their catalog has a lot of stuff that is hard to'find elsewhere.
Although I'm of the opinion from their actual performance that they don't
have a lot of the stuff in stock as they used to.

Their excuses don't hold much water when I can mail an order to All
Electronics and have the parts in 20 days and one mailed to OS
the same day took 2 months and then it was a letter cancelling the order
because 3 of 20 items were out of stock.

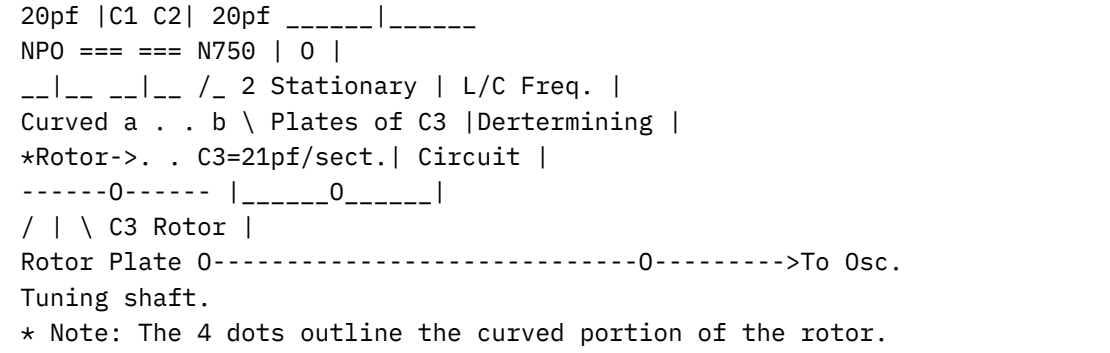
Hi Darrel,
You can make this unit by using a "Differential Capacitor". E.F. Johnson used these in their VFO's. My first experience was with the 6N2 VFO Kit I built in the early 60's and shortly after, the RangerII kit. The differential cap was used in both kits. I show a semi-graphic schematic version of the Differential Cap as it would be connected in an oscillator circuit of a VFO. The differential characteristics come from the way the single rotor meshes with two stator plates. This rotor plate can mesh an equal amount with both plates at half capacitance. Further rotation increases capacitance on one and decreases capacitance on the other and still maintain an average capacitance when summed. The insertion of a 20pf NPO cap (C1) in series with one stator (C3a) and a 20pf N750 cap (C2) in series with the other stator of (C3b) allows the choice of 0 coefficient to a negative coefficient of 750 PPM/degree Celsius, translated Picofarads change per Picofarad of capacitance per degree Celsius. This allows for temperature changes that are positive to be offset by a correct selection of negative compensation. At this point I say go Digital. :) The above method works good but a little slow to find the correct adjustment. I spotted several differential capacitors in the Ocean State Electronics Flyer. Address is below.

Note: Capacitor values were selected at random.



O------O-------------------------O--------->To Osc.
20pf |C1 C2| 20pf ______|______

$*$*$ 30 Weak Signal Challenge (HAM Post) - Now $40 $*$*$

Five weeks have passed since the original posting of this challenge.
During that period, the Web page was accessed over 1000 times.
The weak signal recording has been listen to and processed by
many. Several operators using their best audio filters have been
able to copy my call. And yet, a correct identification of the calling
station has not been made. I am increasing the amount offered to $40
and will continue to escalate the prize until someone cracks the problem.

Details on the challenge can be obtained from my Web page:

http://www.webcom.com/~af9y/

If you do not have a Web Browser, you can ftp the following:

FTP ADR: ftp.webcom.com/pub/af9y/www/

Sound File: unkn422.zip This is the Zipped Wav File

Ref Files: af9ypage.zip GIFs of AF9Y Web Page (with challenge info)
fftdsp38.zip FFTDSP Demo Program
fft422.zip View of unkn422 in next release

The winner will be announce in the UseNet groups carrying this post
and my Web page.

Final Note for those trying their own signal processing techniques:

Many have asked about the WAV file format used for the
A/D recording. The format is a PC Windows standard which
contains 43, 8 bit-bytes of header (which can be thrown away)
followed by a consecutive series of 8 bit A/D data. The sample
rate was 8192 samples/sec.

Good Luck,
de Mike Cook - AF9Y

:it doesn't exist and was a fig-newton of someone else's imagination.

:If binding dissimilar metals, a conductive grease is what is
:prescribed. 73 de Walt - K2WK

Walt: I have here the remains of a tube of Dow Corning 5 Compound,
described on the tube as "a silicone dielectric......5 Compound is used for
insulator and bushing flashover protection".

I used it on antenna connectors from MF thru CB to VHF when I was in the
marine electronics business. Used to stuff PL259/SO239 connectors full of
it, and they would unscrew easily two or three years later, and
that was on Nova Scotia's Cape Island fishing boats - one of the world's
unfriendliest environments for electronics. They would still conduct,
too, as indicated by power and SWR measurements. Admittedly this wasn't
dealing with dissimilar metals, but a daily sloshing with salt water
gives ample opportunity for corrosion. A side-effect, true of any
silicone grease I've met, is that a trace of this stuff on your fingers
means that black plastic electrical tape won't stick to anything you touch!

As to needing conductive grease for corrosion protection, most of us
have used Vaseline or similar petroleum jelly on car battery terminals for
decades. It isn't conductive, but the car still starts.

So the point of this ramble was to resurrect what you hoped was laid to
rest: Dielectric Grease, YES!

1124. Defect in Far Circuits PCB for ARRL Tandem Match

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-27 15:26:30 UTC
From: rdewan@uhura.cc.rochester.edu
Message-ID: <1995Mar27.152630.1026@galileo.cc.rochester.edu>
Source record: 113727

Off and on, I have been putting together the Tandem Match computing
power and SWR meter that is in the current ARRL Handbook and the
Antenna Book. I finally got the system to work and now I am working
on led bar graph and numeric display using lm3914 and icl7107, respectively.

Couple of gothchas:

i) This is the irritating one. I used a pcb available from Far Circuits.
It is a really expensive PCB ($19). An 1/8" line from Test Point 9 to the input
of the 100k resistor for the summing op amp is missing. I won't bother
with you with the time and aggravation it caused me to find it. It is
possible that mine was the only pcb with the defect, but I doubt it as
the pads that should have been connected are well formed and there is
not even a hint of a line.

ii) The power supply section is hokey. The original article in QST,
the Far Circuits version and the current Handbook ('95) versions are
all different from each other. The trick is to get the lm336 to
produce the reference voltages with different supply voltages. The latest
version has a LM334 current source for the +2.5v reference but just a
resistor for the -2.5v. This can be a problem if the V- supply is about
-5v. The resistor between the V- LM336 and the V- supply needs to be
halved to 3K. A much better solution would be to use another current source
such as a LM334 in the -2.5v circuit and program it for 1ma or so.

A hint:
If you are going to use all digital display using LM3914 and ICL7106/7
then you can delete the whole divide portion of the circuit and do
it in the display chips instead. Both these chips have provisions for
external reference which can be set to Vf-Vr and in effect perform the
division.
A related catch: keep the 2n2222 in the divide section to prevent hunting and
spurious noise driven SWR readings when there is no power.

Fun fun fun

From: sjohnson@melpar.esys.com
Message-ID: <D63vAE.CIw@melpar.esys.com>
Source record: 113732

About 10 years ago there was an article in QST about replacing the stock diodes in the TS-830's product detector with hot carrier diodes. Supposedly these diodes create less noise. I did the modification to the 830 and (subjectively) thought the rig was a bit quieter.

Has anyone else had experience with this? I am contemplating repeating the mod. on a newly acquired TS-440S.

: What the accompaning illustration shows is that the radius is actually
: the curvature of the dish. in ascii graphics..

: *
: *
: * *
: *
: *
: |-f-|
: |---C----|

I'd not recommend applying this formula to anything other than the special case of a focal plane dish; one which has the focal point even with the outer edge of the dish and F/D of .25, (f=C in the above rendering). It is only correct for this case.

In general, for standard (not offset feed) dishes the focal point is f = D^2/(16*c), where c is the depth of the dish, measured at the center. Be careful that both the diameter and the depth are measured using points actually on the dish surface.

> | | |
> +--===--+--===--+
> 470R 470R

You might try this:

1) The one side of the XTAL should connect only to C and *not*
to the output of the '04.

2) C could be much larger. Try 0.1 uF, perhaps larger.

3) When I have made similar circuits LS04, I used 2.2K for the feedback
resistors.

4) I also used a 0.1 uF to AC couple between the first two '04s that
have the feedback resistors. This allows each '04 to have
optimum input DC bias for amplifying small changes.

5) It may be that you may have to go to *slower* parts. You could try
using CD4069s (pin compatable with a 74LS04) and 33K feedback
resistors (exact value not important... these parts have very
high input resistances).

32kHz 0.1 uF
+--|O|---------||----+

SM5LYM mikael.landing@teknikum.uu.se wrote:
: Looking for design-equations or design-program for hairpin-filters.
: Are going to build front end filter for 1.8GHz receiver!

I'm not aware of any inexpensive programs capable of accurately designing hairpin filters. I know the Compact Software stuff works, but its in the $15,000 category.

It is certainly possible to design them by trial and error--the early designs were done this way. The spacing between the lines determines the bandwidth. Actually, the width of the hairpin also does, but to a lesser extent. The impedance matching is done by adjusting the tap point. The center frequency is primarily determined by the length of the lines. Jim Davey did the early work, and found that it was quite useful to measure return loss, as opposed to just insertion loss.

It's interesting that the confusion goes a long way back. One of the
Radition Laboratory Series books, (the one on microwave measurement),
says that BNC stood for "Baby type N connector". This book has a
publication date of 1947.

My guess is that's hearsay, as only the Department of Redundancy Department
would call something a "Baby N Connector Connector". Not to mention
the confilict with TNC connectors.

Until someone digs into the archives of the Army Navy RF Cable Coordinating
Committee, and finds out some reference to the orginal design of the UG-88/U,
we'll never know.

<snip!>

Have you called any of your local 2-way radio shops asking for instruction/maintenance manuals for the Master II gear? There is no secret to putting it on 440, if its original frequency was between 450 and 470 MHZ generally all you have to do is order proper crystals for the transmitter and receiver and align it to the new frequency. No parts changes are generally needed. You can look at the existing crystals, if any are still in the equipment, and see how the xtal frequency is related to the output frequency. Matter of fact, most crystal mfr's already have all this info in their data banks and all you have to do is call/write them and tell them you have a MASTR II and hopefully the model numbers off the tx and rx and tell them what frequencies tx & rx you now want and they will do the rest. There are also several outfits that will take your old channel element and re-fit it with the desired new crystal and set it up on frequency for a very reasonable fee, $25 or so per element ($50 for both tx & rx). If I were you I'd call each and every commercial 2-way shop in your area, there must be several or dozens, until I found one willing to sell/rent the information. Often these shops will have a ham or 2 on board that may even be willing to help photocopy pertinent pages, etc. One or more of your area shops will have at one time or another serviced MASTR II's and will have the info or be able to order it for you.
There are many used equipment dealers around that sell MASTR II's and perhaps service literature can be obtained from them too.
Here's one from a recent issue of Mobile Radio Technology magazine:
SCHAEFFER RADIO Co.
1301 Grant St.
Box 395
Denver IA 50622
(319) 984-6220

Or:
AIR COMM
4614 E. McDowell Rd
Phoenix AZ 85008
(602) 275-4505

If you have prior radio service experience it should not be too difficult to set these up with no docs at all.

BTW, as one having 20+ years of servicing both GE and Batwing (Motorola) equipment I would not rush to say one is better than the other... it depends on which model radio you are referring to. SOME of the GE mobiles are more easily made into repeaters because they have completely separate transmitter and receiver sections, allowing

isolation for better repeater operation. It's been a while, but seems like the MASTRII fits in that category. I can't think of a Motorola mobile except for the Micors that are easily made into repeaters (also the older Motrans) but the Micor is otherwise not one of my favorite radios. But as far as service and performance go Motorolas haven't dominated 70% or more of the 2-way market for the last 30 years just because they have slick salespeople...

Hello all,

So i am working with an MAR8.
Voltage i use is 10V. The resistor to the MAR (max. of 7.5V) is 390ohm.

The input signal to the MAR is coming from a dual gate mosfet (with in between a 2db atten.)
; the gain of the mosfet is
variable with the voltage on gate 2.

When the input signal for the MAR is increased by the output of the mosfet the
DC on the MAR is decreasing, from 7.2V to 3V!!!.

I dont know what is happening and why it is happening........

Also the gain is not so high i was aspecting(only 1.5*Uinput)???? STRANGE..

Is the anyone who can explain this future????

Tnx from PA3GSB the johan

Well, whipping out trusty old Ohm's Law, it looks like the MAR is drawing
an extra 10 ma when you crank up the input signal. Could it possibly be
that you are *DC coupling* the FET to the MAR? It sounds like that when
you adjust the gate 2 bias, you're changing the FET's DC output voltage,
and that's driving the MAR into heavy conduction. You need a chip coupling
capacitor between the FET drain and the MAR input.

Gary

There are loads of QST articals on how power amps. Everything from a 2C39A to 3CX1500A7.
See ARRL manuals. I once bought a number of large power tubes
1500W tetrodes, that were used at 1215MHz, but never done anything with them.

There was once an artical in QST that used a 4CX250B as a 2m amp, but that could be used as
a tripler to 70cm. I could probably dig a reference out. e-mail me directly
if you want it.

I on once looked at using a stripline design on 144 and 432 MHz, thinking as one is
3x the other, a line resonating at 2m would resonate at 70cm too. When I looked more
closely at the maths, the third harmonic resonance is *not* exactly on the third harmonic,
so it's not as easy as I thought.

There are a few 50Mhz/144Mhz designs areound too. Again I can probably find it. I have
a small collection of high power amp designs.

Nice, factual, interesting!

About 6 months ago I posted a little suggestion on one of the hifi
groups. They *do* contain some reasonable (I.E. can reason) people, but
there is a fairly loud group of people with little factual knowledge who
have latched on to various beliefs with a tenacity challenging the most
extreme religious fanatic. One of the most popular beliefs is that any
valve amplifier, no matter how badly designed, HAS to be better than any
possible semiconductor-based design.

My suggestion was that with the Russians searching for any and all
means of earning hard currency, one could get them to take valves up to
MIR to be exposed to space for evacuation and outgassing then sealing,
to be brought back to earth and sold at a premium price, because, surely,
natural vacuum must sound better than man-made stuff.

They couldn't handle British humour, too many swallowed it.

On the good side, someone responded about possible oil contamination
from a diff pump, a second pointed out that low earth orbit isn't such
a wonderful vacuum. Only two, depressing, n'est-ce pas?

Cheers

"COMMUNICATIONS QUARTERLY" Reports a Milestone in Communications Receiver Development!

The upcoming Spring 1995 issue of "COMMUNICATIONS QUARTERLY" will feature an article titled: "The Watkins-Johnson HF-1000A Milestone in Communications Receiver Development." This informative piece is written by Scott D. Prather, KB9Y, an author who is frequently published in the Quarterly.

Those of you who would like to learn about this new receiver will find a plethora of information that will explain in detail what it is and how it works. Mr. Prather begins his article: "The Watkins-Johnson HF-1000 is the first affordable, stand-alone commercial receiver to use digital signal processing (DSP) at the IF level. In the HF-1000, DSP provides IF selectivity, demodulation, noise blanking, fine tuning, passband tuning, and signal strength calculation, along with several other features ... The use of DSP in the HF-1000 represents a major turning point in receiver technology." One key piece of information offered by Mr. Prather is that the unit is relatively simple to use. He explains: "I found I could execute about 90 percent of the receiver's features without referencing the manual." In conclusion, the author continues: "So, what's it like to use a digital receiver? It's unbelievable! ... the HF-1000 [is] the most enjoyable receiver I've ever operated." "Watkins-Johnson has made a brilliant move into the future of communications receivers."

The article features such topics as: an overview of the HF-1000, the HF-1000 RF assembly, a brief tutorial on Digital Signal Processing, the HF-1000 digital control assembly, and using the HF-1000. Other features include a schematic of the Siliconix Si8901 high-intercept mixer and photographs of the RF and digital assemblies within the HF-1000.

If you'd like to know more, pick up your copy of "Communications Quarterly" -- on newsstands in May.

>do not want to have to mortgage my home for the parts!!

A nice one appeared in QST a couple of years back. It used a 3cx800
to put out a kw.

Three other possibilities:
i) Use the 3-500z amp schematic in the handbook. Leave one tube out
and redesign the input/output tank to work with one less tube (twice the
input and plate load). The handbook has the charts to redesign the
tanks. You could save further by skimping on the power supply current
rating.

ii) Build a solid state one according to Motorola app notes. Partial
kits are available from Communication Concepts Inc (they regularly
advertise in the QST)

iii) buy a used sb300 for $300. May be the easiest option of all.
Redo the swithching if you want qsk.

Best of luck

Hi,
The MAR-8 requires a voltage of 7.5 volts and a current of 36 mA.
A 390 ohm resistor is too big. With 10 volts on the input, you need a
resistor value of (10-7.5v)/0.036A = 70 ohms.
Also, the MAR-8 is the only MAR MMIC which is not unconditionally
stable and goes into oscillation easily. If you experience this, there
was a circuit in QST which provides feedback. It is simply a 2.7K ohm
resistor in series with a 0.01 uF capacitor bridged from the iinput to
the output of the MAR-8. It reduces total gain by 4-5 dB but kills the
oscillation. I have used this successfully several times.
But I think the trouble is really too large a bias resistor in
the input line. Try 70 ohms and see how it goes!

It doesn't have to be a chip cap, but those are usually the best
kind.

I second Gary's suggestion; the dead giveaway is the decreasing
output voltage with increasing input voltage....

If there is a capacitor already, then make sure it isn't leaking
or shorted.

Subject: Wireless tach/altim. project
Newsgroups: rec.models.rc
Summary:
Keywords:
X-Newsreader: TIN [version 1.2 PL2]

Greetings Everyone:

I am a junior Electrical Engineering major at Bucknell University and I plan on designing and building a telemtry system for RC aircraft as a senior project next year. I plan on featuring altitude, tachometer and battery monitoring functions on the system, primarily because I have ideas/plans for each of these sensors. Airspeed is a tricky one as I would have to mess with atmospheric pressure, humidity...etc(I think)

What I am looking for is any technical info on RC tx/rx systems. I hope for simplicity's sake that I will be able to use an old two channel radio set as the foundation of my wireless data link. While the system will be transmitting digital information, I think that I may be able to use phase shift (PSK) or frequency shift (FSK) keying on a hacked AM or FM tx/rx. I will have only two data levels, "0" and "1", so I think that I should just be able to use two distinct frequencies or phase shifts modulated around a carrier freq. Any suggestions, comments or ideas on this? Are there any publications in the RC world that get into the meat of RC gear info?

Additional concerns are: frequency concerns...should I use 27 Mhz, 72 or 50?

Thanks for the help folks.

Hee, I didn't realize ANY of the MAR's were "UNCONDITIONALLY stable"
as advertised by the early full page ads. Haven't messed with them in
several years now but when they first came out we bought several of the
Mini-Circuits MAR experimenter's kits and found they ALL were quite
touchy about PC layout. If the PC strips feeding input and output weren't
pretty close to perfect they would oscillate like crazy; hardly
"unconditionally stable". Of course I've noticed similar behavior with
"unconditionally stable" op amps too. I think "Unconditionally stable"
is sorta like cold fusion or anti-gravity... awfully difficult to find
in real life.

jl> nichrome wire? I'll be using it to tame parasitics in an old Gonset KW.

Nichrome wire might be available from an electrical supply house. Even if
they do not have it, they may be able to direct you to somebody that does.

If this does not work, buy a new clothes dryer heater element. This may be
more wire than you want, but at least it is there. Clothes dryer elements
are available in several sizes and configurations from almost any supplier
of repair parts for dryers. I have replaced two in my own dryer over a
twenty year period.

jl> I tried salvaging this from a toaster, but it's impossible to solder
jl> after it's been oxidized by heat (even new toasters have been heated
jl> at least once).

I have never seen nichrome that has been soldered. I have seen connections
to nichrome, and I have made connections to nichrome, and they are always
screw/nut/washer clamps. I have tried to solder to aluminum and failed.
I have tried to solder to chrome and failed. Tin...yes. Silver...yes.
Nichrome, I would at least be surprised.

Since you already have toaster elements, and you can get nuts and screws,
you really do not need to call supply houses.

jl> Any and all help will be appreciated.

you are welcome

: components, receiver and CW xmtr.
: Erik

Erik. You are about to make a very common mistake. One that has been known to wreck a beginner's self-confdence and discourage him from building anything ever again. It can be avoided, though.

The smallest number of components rarely means the simplest circuit to get going. Components are cheap, but confusion is very expensive. As a beginner you need to build things that are sure-fire workers, because these will encourage you to go further. It helps a lot if their workings are well explained, so that you can trace any mistakes you've made and get the thing going. It's a great feeling when you've ovecome a few obstacles and got your first radio going without help.

Imagine I designed two different radios:

1) I try to use the minimum number of components. Performance just marginal, as much gain as possible squeezed out of each stage. Perhaps not only do you need the right part number transistors, but also ones with higher than average performance for their types. You'd need to get duplicate parts, hopefully from different manufacturer's batches and sit there selecting them until the radio works. Perhaps you may need to mess around with the values of some resistors to suit the transistors you have got. (There is far more variation in characteristics between transistors supposedly of the same type than there is between resistors supposedly of the same value)

********** This is no exaggeration, some published circuits really have been this bad ! Just because somerthing is published does not mean that it's going to work. If something you try doesn't work, it is not necessarily your fault.

2) I try to design a sure-fire project with plenty of allowance for the tolerences of all components, divided up into clearly separated stages, each with a specific function and careful explanation of how it works. Each stage of modest gain, but with more stages to give the required total gain. I write about how to test it with simple equipment, one stage at a time, until the whole thing is complete and working.

Do you get the idea ?

You need to be careful where you get designs from. The ARRL is pretty careful about what it publishes, and employs a variety of very competent people who check and edit things before publication.

Your new (1995 not 1996, I expect) Handbook is a complete re-write, not the usual annual update. The style has changed a lot, and while the old version was great fun, it did tend to just throw circuits at the readers, and leave them to sort them out for themselves. The new book is a lot more thoughtful and a lot of care has been taken to explain how circuits work, and what compromises the designer had to make.

Can I repeat someone before's advice to read it several times. Each time you'll pick up a lot more, built on the foundations laid by the previous times.

Have Fun!

David GM4ZNX

: Hee, I didn't realize ANY of the MAR's were "UNCONDITIONALLY stable"
: as advertised by the early full page ads. Haven't messed with them in
: several years now but when they first came out we bought several of the
: Mini-Circuits MAR experimenter's kits and found they ALL were quite
: touchy about PC layout. If the PC strips feeding input and output weren't
: pretty close to perfect they would oscillate like crazy; hardly
: "unconditionally stable". Of course I've noticed similar behavior with
: "unconditionally stable" op amps too. I think "Unconditionally stable"
: is sorta like cold fusion or anti-gravity... awfully difficult to find
: in real life.

No, it's not that hard to find. Unconditionally stable doesn't mean you
can't make an oscillator out of the part if you try. It doesn't mean
that your "amplifier" won't oscillate if you do things wrong.
What it means, generally, is that the part will not oscillate for any
combination of passive (reflection coefficient <= 1) input and output
loads at any frequency apart from external feedback. One way this
quality can be represented is by analyzing the Linville Stability
Factor.

To do this requires a fixture which does not provide feedback to the
DUT. The fixture should also be representative of the application
environment if the results are to be reasonably useful. By measuring
two port S parameters for the DUT in this environment, Linville's factor
can be calculated. This can verify that the device will not oscillate
apart from external feedback. Available active device measurement
software/hardware packages can do this for you.
It is important to recognize that there are a variety of possible
sources for external feedback which could cause an unconditionally
stable part to oscillate. Input/output coupling by way of parasitic
capacitance is a familiar one but common lead impedance; not
sufficiently grounding the common leads, is another. Poor power supply
decoupling can be a problem too.

In the distant past I've carefully measured the MAR-8 and found the
advertized numbers to be reasonably close, though on the samples I
measured, I did find the range of potential instability exceeded that
which was advertized. I was measuring in a carefully constructed
and measured fixture with the measurement plane moved to the the edge
of the part body by using deembedding. The common leads and the body
of the DUT were effectively trapped in a conductive wall of the fixture.
All measurements were after careful calibration.

As I remember, I only measured at a few different bias points however it
is likely that near worst cast behaviour was obtained.
If someone really wants details, I can probably find the data.

1164. Need software for circuit design

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-29 00:00:00 UTC
From: drake@oasys.dt.navy.mil
Message-ID: <3lcj36INN1qc@oasys.dt.navy.mil>
Source record: 113672

My 13 yr old asked me to post a request for a circuit design program which will run on a PC. He can't find anything locally at the computer stores, but did download a shareware program last night from a BBS (I don't know what the title is). If anyone knows of one or can make a suggestion about where to look please respond via email.

Thanks

John Drake

drake@oasys.dt.navy.mil

3HA5 High Mu Triode

Fil volts 2.7
Fil ma 450
Max plate watts 2.6
Max plate volts 220
Element capacitances pf
Input 4.3
Output 2.9
Grid-Plate 0.36

This tube was intended for Class A amplifier service. The following
are typical operating characteristics.

Plate volts 135
Grid bias -1.0
Plate current ma 11.5
Gm 14,500 umhos

All this data from the GE Essential Characteristics tube manual.

The 3CX100A5 is still a popular power triode for the upper UHF spectrum, up to about 2.5 GHz. The glass envelope version is the 2C39 which should be avoided for most uses. I haven't bought any brandy new ones in many a year, but new surplus ones are fairly easy to find, and should run under $25 in sealed US government pouches. Guaranteed good pulls should cost under $10. Check a major hamfest, like Dayton.

On cable I saw as a doctor told us from the Space Shuttle that radio broadcasters are licensed to broadcast through time. Having gone to school for electronics... they never actually say that as he put it, but the instructor was HEARING my thoughts telepathicly, picking at them and made sure I understood that they were my thoughts and not broadcasted thoughts that everyone heard.

No one is supposed to tell anyone about this. Resonance apparently is the techneque for getting a dipole through time. He did say it was done with capacitors... and apparently is pretty easy.

At the same College was where police go to school for Drugs alcohol and crime. Probably their instructor tells them about time communication and Telepathy. (robbing thoughts)

Robbing thoughts makes a person suicidal and homicidal. The TV news who apparently is telling our Congressmen what to do because they own the broadcasting weapon... waged war on us. They hear YOUR thoughts as you sit and watch the TV and they can be in a different time period.

While they were attacking us... I could not tell anyone about this, because of how crazy it sounds for them to be doing.

Sounds like you need both the service manual and a user's manual for
the GP300. Try Motorola National Parts at (800) 422-4210.

"Communications Quarterly" Columnist to Speak at
Dayton Hamvention - K1BQT on "Hi-tech Scrounging"

Attention "Quarterly Devices" Fans: If you're headed to the Dayton Hamvention this year, check out the VHF/UHF forum of the Midwest VHF/UHF Society. Rick Littlefield, K1BQT, "Quarterly Devices" columnist for "Communications Quarterly" magazine, will share the secrets of "high tech scrounging" or, as he calls it, "that artful pocess every resourceful designer must master i order to gain access to the world of high-tech R&D."

Learn what products are fair game for sample requests, where to fing out about new electronic components, and how to obtain samples for your latest project. K1BQT, a master scrounger himself, will teach you some tricks of the trade. Check your Hamvention program for date, time and place.

Subject: ### Help wanted: Construction of a Gel cell charger...

>>I've recently acquired a 12V 10Ah sealed lead acid battery, and am
>>interested in constructing a charger for it.

I am NOT technically-minded enough to answer your electronics questions.

BUT - I have experience with "keeping it simple." No, this suggestion
isn't a homebrew idea, but it sure is simple.

Two items have given me positive results with my storgae batteries - the
Canadian Exide MEGA-CELL Fully-Automatic Charger, available at Auto
Parts stores nationally, works marvelously for me on my two Yuasa
38-amp-hour batteries. I set it on "Fully-Automatic / Conditioning,"
and trickle/condition two cells in parallel.

The other item is available at your local Kubota lawnmower shop. (I am
sure there are many others out there other than the Kubota.) "Battery
Pal" is their trickle unit, and I have had good results with it. About
$25.00 retail.

HIGHLIGHTS OF MAY, 1995 "CQ" MAGAZINE

Copyright 1995 by CQ
Communications, Inc.

Results of the 1994 CQ World-Wide WPX CW Contest highlight the May, 1995, issue of "CQ", along with a fascinating report on the 9G5TL DXpedition to Ghana for the 1994 CQ World-Wide DX Contest.

Operating a DXpedition station during a major contest is the dream of many an avid DXer and contester. But imagine doing it from a country that, just two years earlier, had considered it a crime to operate a ham radio station. "The 9G5TL Story," by Warren Hill, KF7AY, tells the exciting tale of planning and preparing for this ham radio adventure, the thrills of operating from a rare country during the biggest contest of them all, and of the long-term benefits of the operation to ham radio in Ghana.

The 1995 CQ WW WPX Contest is now history (for the uninitiated, that's short for the CQ World-Wide Worked All Prefixes Contest, in which you try to contact as many stations with as many different callsign prefixes as you can during a 48-hour period). And the results are in from the 1994 event. May's "CQ" magazine reports fully on the CW portion of the contest. Here's a brief list of the trophy winners:

Single Operator, All Band --
-- World: John Crovelli (W2GD), P40W
-- USA: Tyler Stewart, KF3P
-- Oceania: Michael Sato, AH6MZ
-- Canada: John Sluymer, XL3EJ
-- Canada, low power: Gary Caldwell, XL7NTT
-- Japan: Satoshi Hara, JH5FXP

Single Operator, Single Band --
-- World: Martin Monsalvo AZ4F (LW9EUJ)
-- World, 7 MHz: Bob Furzer, 9K2ZZ
-- World, 3.5 MHz: Pavel Vachal, OK1DXS
-- Oceania: Boyet Lorenzo, 4F3AAL
-- USA: John Yodis, K2VV

-- USA, 28 MHz: Phil Koch, K3UA
-- USA, 21 MHz: Scott Jones, WR3G

: >anywhere else. Does Heath still exist? Are they still making kits? ....

: The Heath Company still exists, but they are no longer making "HeathKits".
: ......

Yes I remember (1970?) building the 5 HF band receiver. It used tubes
even for the power supply. No circuit board only point to point wiring.
A few years ago my last kit was a Heath TNC which was produced before they
closed up the kit shop.

Things change and I will always remember thoses kits with very detailed
step by step instructions. Some of the small kit producers are providing
very good low cost kits. But Heath has set the standard. R.I.P.

On the first: Having operated on that band for several years (several years ago - Beacon 'CT' on 177.75, CCW and BPSK from Arizona and Utah - and having heard transcontinental LowFER DX and having been heard...) The FM will work, but it will go a short distance.

The problems with FM will not necessarily be the limited distance (several 10's of miles are likely, assuming that you have a *good* antenna/ground system and that the receiver is also good...) but rather the conflicting requirements of an efficient antenna system (for lhighest radiation resistance) and sufficient bandwidth for an FM signal to exist.

A typical "good" LowFER station (is there such a thing?:-) has a 35 foot mast with a 15 foot radius tophat structure, and a slightly-elevated ground system (NOT buried... ground is pretty lossy...) with a base-fed antenna with a loading coil at the base.

The loading coil, is, at a minimum, wound using #14 (or heavier) solid wire (or, better yet, if you can afford it, Litz wire!!!), preferably using a basket-weave technique (to reduce distributed capacitance). With a 1 watt Input (>95% efficiency transmitters *are* available, and easily built!). Once you have done all of this, you should reasonably expect a current of greater than 150 milliamps (RF).

You *could* use a TV horizontal oscillator coil (which work, but they suck rocks...)

An efficient antenna system also implies a very high Q. A High-Q also implies narrow bandwidth. Narrow bandwidth and FM do not mix. To cite an example, my Lowfer station wasn't *really* good on the TX side (Not a really good ground, not as clear of trees as I'd like, an "OK" litz-wire loading coil... I got an RF current of about 200 mills...) when I ran SSB (using my TR-7... It *is* possible...) I had a serious problem with 'sideband cutting'... I could tune for muffled sound, or tinny sound, but I had to comprimise... and that's just a few KHz... FM will want at least 6-8 KHz even if you *do* run really narrow deviation (i.e. 1 KHz or so... Keep in mind that Carson's rule says that even with 1 Hz deviation, you'll still take about 6 KHz of bandwidth with a 3 KHz hi-frequency response .. Unfortunately, a good antenna usually rules out a wide frequency response... Maybe you'll want to try one of those TV horizontal oscillator coils after all...

As for BNC: Bayonet Neil Concleman (sp?) - It's in the ARRL UHF-Microwave handbook.

As is info on using dishes for microwave and locating their feedhorn...

A quick and dirty way of locating the feedpoint is also to hold a small piece of white paper in front of the dish (a half sheet of notebook paper works...) while pointing it at the sun... Unless your dish is flat-black, you'll be able to "focus" the sun on the paper to some extent... I did this experimentally, and it agreed very well with the info in the ARRL UHF-Microwave handbook...

<Clint>

turner@vsat.ussc.com

P.S. I seem to recall some tricks done by Longwave Broadcasters to 'widen' their antenna system's frequency response without extreme detriment to efficiency... I'd have to research that to 'remember' it, though...

The Motorola bulletins provide lots of data, parts layouts, etc., on all kinds of amps. Communications Concepts, Inc., in Ohio provides kits for some of these; I think a 300 watt amp running off 28 or 50 volts runs about $350, without output filters or heat sink (?). Get their most recent catalog. Of course, nothing runs at such a low gain as to take 100 watts in for 300-500 watts out -- you gotta crank your drive down, OM!

Hi Zack.

Oke tnx for your reply.

The only thing is the maximum voltage on the MAR8 is 7.5V.
When the resistor is too low in resistance the Umax is probably exeeded which can damage the MAR amplifier???

Can that be a problem?

1183. Toko 1159A adjustments

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-30 00:00:00 UTC
From: mckee@fc.hp.com
Message-ID: <3lenhv$k3q@tadpole.fc.hp.com>
Source record: 113686

I have a 2M transverter with a Toko 1159A filter in it. This filter is centered at 138 MHZ, and appears to roll off before 148 MHZ. It has two screws on it which allow it it be tweaked. Unfortunatly, I don't have a datasheet for it and don't know what it is that the screws actually adjust. I hope its something simple like the position of the two skirts, but I thought I'd ask if anyone knows for sure...

1184. Irradiated Wire ??

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-30 00:00:00 UTC
From: <>
Message-ID: <3leqdk$e1g@xap.xyplex.com>
Source record: 113687

I bought a spool of nice 16-gauge insulated stranded wire from a surplus electronics shop. When I got home, I noticed the manufacturer's byline on the spool said "leaders in irradiated wire". It didn't say whether this particular spool was irradiated.

But if it is, is this anything to worry about? Will my antennas glow in the dark?

1185. 100 Watt HF Amp

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-30 00:00:00 UTC
From: CNS@psimemphis.COM
Message-ID: <199503301128.LAA20948@chaos.magibox.net>
Source record: 113688

I think I have a need that others might share.

I'd like to try to find a design to build a HF amp to take a 1-5W HF QRP transmitter to 50-100W. I've built a 5/40W VHF booster amp and it works very well. 5-100 would probably require 2-3 stages but could use relatively inexpensive transitors. A single band amp would be fairly easy, but a nice feature would be a multiband tuner.

Nathan Sykes email: cns@psimemphis.com

1186. Building SHARP reject filter for 13.845 MHz

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-03-30 00:00:00 UTC
From: dgf@netcom.com
Message-ID: <dgfD69IwC.4qz@netcom.com>
Source record: 113689

I play with direct conversion transceivers such as the old Ten-Tec Power Mite series. In my location (Denver), I get interference from a shortwave radio station (WWCR in Nashville, TN.) that runs on 13.845 MHz and is very strong much of the time (causing AM detection in the receivers). I suspect they are in the megawatt range.

To add insult to injury, WWCR is christian broadcasting (I think the callsign is meant to say "Christian Radio" for CR).

Anyway, it occured to me that I might be able to build a sharp notch filter out of a single series resonant 13.845 MHz crystal. I don't need tunability - just 20-30dB deep notch within 10 kHz of 13.845.

I have no other sources of interference like this, so if I notch out 13.845, I'll be happy. I'll just consider it my contribution to the church.

If I transform the 50 ohm receiver path up to 500 ohms or so, wire the crystal to shunt to ground, then transform back down to 50 ohms (using broadband toroid transformers), will I achieve my desired effect?

: in the dark?

Well, I don't know what irradiated wire is but it may be wire that has been exposed to radiation. Things exposed to radiation don't glow unless they are "activated" by the radiation. I doubt that the wire has been activated. If it were, it would be radioactive material (no not radioactive as uses 2m often:)). I wouldn't worry about it being irradiated.

Maybe it was irradiated to strengthen it. I belive there are techniques that use radiation to harden metals. Radiation is also used to purify things, so maybe the wire was intended for use in a sanitary environment (i.e. medical).

It would be interesting to know the applications of irradiated wire and if it really is what the name implies.

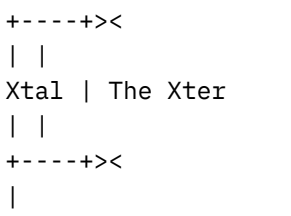
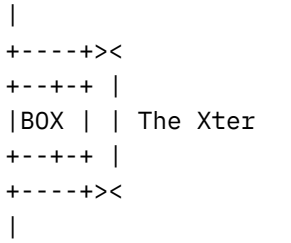
From: papo@bigcat.bellcore.com
Message-ID: <3leueu$fe6@athos.cc.bellcore.com>
Source record: 113691

Howdy:

I got this ye olde CONAR transmitter for 15 bucks and I would like
to plug a VFO in it. Right now the transmitter has a port in which
crystals are inserted.



What I would like to have is to be able to have a VFO in which the
only thing I have to do is to insert a box to the terminals
and that's it.



Although I saw the circuit of the 80 meter xter with VFO on the Amateur Radio
page, I was not able to make head and tails. Somebody sugested to use
a chip, I think it was the U06 something, but I do not
know where to find the specs. Anyway, if anybody has a good idea
about anything, just let me know.

Message-ID: <3lf4dv$7qv@newshost.lanl.gov>
Source record: 113693

Don't worry radiation comes in many forms an flavors including heat. I suspect this logo has to do with an annealing process. Not all radiation is ionizing radiation which is what you were refering to. There might be some application for activated wire but you would not get it on a spool cheaply. If you want to watch out for something beware of Mexican rebar. We found a load of it contaminated with Cobalt-60 a few years ago.

My opinions only not a LANL policy statement

JJ>
JJ>---
JJ> * Origin: HamLink RBBS - 612/HAM-0000 v.34 St. Paul, MN
JJ>(1:282/100.0)
Well there seems to be a bit of confusion over what constitutes
"unconditionally stable". In dealing with the Mar/Mav series of
Mini-Ckts amps, this term refers to the matching of the input and output
of the device. That is the value of S11 and S22. Most of these amps are
designed to work in a 50 Ohm system, and the "unconditionally stable"
commment refers to the fact that the mag and phase of the S11 and S22
parameters can vary from their matched values, without the amp breaking
into oscillation. It does not however mean that you can't buid an
oscillator out of them wheather or not you intended to! Running output
leads next to input leads, coupling output coils to inputs, etc. can all
easilly make these guys oscillate.
I have found that carefull construction over a large ground plane
generally works good. In stubborn cases I have added small value caps
form the output lead, right at the device to ground. Not a solid
engineering fix, but seems to be a quick fix for narrow band

applications.
Also I have found that the Mar/Mav line amps are quite easy to blow up
but not so easy to tell if they are good or bad.... I usually try a new
device if I suspect that it may be popped.
By the way Mini-Ckts offers some graet lit. on these amps, free for the
asking.

Carl:

The ARRL handbook has several tube and solid-state based amps (I haven't seen this years' handbook but certainly past editions have had construction articles.) Another approach would be to contact some of the big tube manufacturers like eimac. I'm sure they would have tons of application notes probably free for the asking. Hope this gets you closer to getting started. 73

ARE YOU SEEKING A CAREER OPPORTUNITY IN RF ENGINEERING?
Your interests in amateur radio maybe relevent to an exciting career.

If you have 2 to 5 years or more experience in RF Engineering and a passion for Wireless Data Communications, then McCaw Cellular Communications would like to talk to you. The Wireless Data Division of McCaw currently has several RF Engineering employment opportunities in the Seattle Area at our headquarters. These opportunities are in CDPD Systems Performance Engineering and RF Test Engineering.

As the champion of Cellular Digital Packet Data (CDPD) technology, McCaw is the recognized innovator in wireless communications. Our new alliance with AT&T brings an even greater opportunity for technical challenge and achievement. We're seeking highly motivated individuals to work in our open, supportive and dynamic enviornment.

Qualifications should include experience with RF systems design or cellular system engineering. Your background in any of the following will be helpful: UHF analog and digital radio systems and telephony; RF test and measurement; Packet switching and router-based networking; MS-DOS/Windows or Unix operating systems; experience with Ericsson and/or AT&T cellular equipment desireable; MSEE or BSEE required.

To apply, please send your resume and cover letter to katherine.deforest@airdata.com or mail it to People Development, McCaw Cellular Communications, 10230 NE Points Drive, Kirkland, WA 98033. Attention: Katherine DeForest. No phone calls please.

You might try locating the real problem. Nichrome is a poor shotgun approach. If the amp uses 572's the self neutralizing frequency is below 30 MHz. It is hard to stabalize an amp that operates above or close to the self neutralizing frequency. Try the following: Short wide anode to tuning capacitor lead. Short wide grid pin to chassis connections. Neutralize the tubes (see the Ameritron 811H, Heath Warrior, and othe 811 amps for circuits).

Also: Add a small mica cap in series with the resistor in the parasitic supressors. This allows you to use increased loading of the supressor coil at low VHF frequencies without excessive resistor heating. If you want more details E-mail me or call me at 404-760-7355.

We use irradiated coax and wire because the insulation doesn't melt when the assembly line workers talk to each other while holding the soldering pencils on the wire. It's has a higher insulation melting temperature but doesn't cost as much as teflon. So far as I know it doesn't glow in the dark, unless they hold the blowtorches on through most of the day. ;-)

: between two GP300s. Can I, for example, us QuickCall or whatever it's
: called to turn on my partner's radio? Can Burst tones be used to do
: this? I know the Ritron Patriots are capable of this QuickCall style
: paging, but is the GP300?
The GP300 has a number of signalling decode features that are
primarily documented (like most current M radios) in the RSS
manual (radio service sofware)

The only dynamic encode is DTMF -which the radio is not able to
decode (last time I looked)

I am assuming we are talking about the US domestic model since I
believe that the European version may have the capibility for
unit to unit signalling (5/6 tone) via the keypad/display

The hardware service manual is just for fixing broken HW with
the usual parts and schematics. These do not usually document
the radio functionality to well on current production radios.

Good Luck

Hi,

This is another request for a design for a receiver circuit that
will detect a 5KHz carrier signal.

It needs to be a compact and low-power. It's detecting a 5KHz
pulse that's being generated from a very weak transmitting source.

I had a promising reply from Paul Wenz but am unable to contact
him via email. Paul, if you read this can you email me your
fax or email address where I can contact you.

Thanks in advance,

Peter.

A great little amp is the Motorola AN-762 (Application Notes) amp which
appears in the Motorola RF Devices Manual, and was in the ARRL Handbook
in the late 80's.

It uses two MRF454 transistors in push-pull and puts out 100-140 watts
for 5 watts of drive. I made a circuit board from the template in the
ARRL handbook and had many of the parts in my junquebox. The rest I think
I got from Communications Concepts, Inc.

This is a broad-band amp (1.8-30 MHz) and has no tuning, but you do need
a lowpass filter on the output.

I have been very pleased with the performance of this amp!

Good luck. I hope this helps!

Try an Oak Hills Research QRP kit. They are Heath quality parts and all of
the kits I have from them have been no_problem kits. Phone of order or catalog
is (616) 796-0920. They also have great watt meters and a killer audio filter
kit. Both are in daily use here.

The 3CX100A5 (aka 2C39 or 7289) is a GREAT tube! It is still just about the only way for amateurs to generate QRO on the lower microwaves (23 and 13cms) economically. They yield up to 13dB gain in a good circuit.

I'm using a single one in a cavity on 1296MHz SSB/CW and have an on-going project to build a pair- I'll finish the metalwork some day!

As with all tubes a main factor limiting output power is temperature. These tubes can be used with just convection cooling to about 10W and with force-air cooling to about 100W output. Some amateurs unscrew the air cooling fins and replace them with a water cooling coil. I'm told you can get lotsmore power out that way!

They also make very easy to build amplifiers for 70cms and I guess 2metres. To build a 432 amp all you do is mount the tube at one end of a half-wave strip-line (about 195cms long and 40cms wide). You can even solder the tube in to a piece of PCB and throw both tube and stripline away when it nees changing. Being a triode bias is very easy- ground the grid ring, and bias the cathode with a simple transistor. With 5.9V on the heater and abut 1kV on the anode you can't fail!

As you might have gathered I like these tubes (g). As for availability, well I guess you COULD buy a new one :-(But the surplus ones I've got were given to me. There are always 2C39s for sale at ham-fests and the going rate for a used good one in the UK is about UKP 5 (8 dollars).

Happy building!

This is just a comment but it sounds like you might be getting enough signal
in the reciever gunplexer to be rectified. How far apart are the units?
Your post did not state that the signal strenth is good when the recieve
gunplexer is on but hopefully you have a good distance before things
start to get marginal for you.
I am also interested in doing something similar to your project and would
like to hear more on your progress and range. I would also be interested
if you plan on making a permanant link out of these units.

I've got quite a few helical resonators around the house. I think you usually end up seeing square or square with angled corners in production devices bceause that is easier to make in mass production.

>Also, the covers are said to be optional.

I wouldn't omit the covers. The resonator is usually tuned with a very small amount of capacitance, without a cover it would be easy to detune your resonator.

>Comments (with regard to round or square, and covers) are welcome!

Why not take a break from looking for TV sets and start looking for discarded land mobile radios? The front end out of a GE Mastr Exec II or MVP is nice, the front end from a Micor is good, etc. There's lots of resonators out there; the VHF High band business resonators will either tune to 147MHz directly or with a minimum of modification.

Hey, 147MHz? That's 2m. What are you doing on 2m?

>
>Norm
>cramer@dseg.ti.com

It's the insulation that is irradiated. Ordinary polyethylene has vary good
electrical properties but it is stiff and it melts at a low temperature.
The molecules of polyethylene are very long and straight, if you can tie them
together at random intervals (called cross-linking) the polymer becomes more
like rubber, flexible and resistant to melting. One way to cross link is to
use chemical agents like peroxides and heat the polymer after it is applied
to the wire. The other way is to expose it to radiation after it is extruded
onto the wire. The radiation is most often from an electron accelerator, not
from radioactive substances.

We're being shown that the radio and TV can communicate through time and they seem very nasty. The only cure for it, is for more people to do it. They rob thoughts of people who listen to the radio and TV and talk right back from old movies and radio shows.

I see how well they do it. They seem insane because hearing thoughts is an insane thing to do, and they loose their sence of reality. But computer messages and software can also be sent through time because it can be broadcast.

Can anyone give me some hints? I called NBC in Jacksonville and they asked me if I wanted to buy some information, and that the ARE doing just that. They also said that they were just the carriers for the movies, but the TV news also grilled me and talked back.

If we all have to do it... to stay alive... then maybe we just better get together and give each other some needed information on the subject.

I've got a few things for sale:

- One Ranger 2950 ten meter rig in absolute mint condition. Has instructions, documentation, all original brackets and accessories and original box. I am selling this radio as a package deal with a 250 watt 10 meter HF amp. This amp has a built-in pre-amp, and a toggle switch for SSB/AM operation. This amplifier may ONLY be used by a licenced amateur operator. You also get a high power SWR/power meter (up to 1000 watts) with mounting bracket. All this for $400.00.

- Pro-34 hand held 200 channel fully programable scanner. This scanner covers all the usual frequencies as well as 800Mhz. It is cellular restorable. $175.00.

- Uniden Bearcat 200XLT hand held 200 channel fully programable scanner. This scanner also covers all the usual frequencies and 800 Mhz. It is also cellular restorable. $175.00.

Please email me if you are interested in any or all of the above. Thanks!

>production.

Hi Dana: From further reading I've learned that the disadvantage
of square resonators is the seam; apparently it lowers the Q, and
to overcome the loss one is supposed to silver-solder the seam.
So I'll use copper *tubing*.

>>Also, the covers are said to be optional.

>I wouldn't omit the covers. The resonator is usually tuned with a
>very small amount of capacitance, without a cover it would be
>easy to detune your resonator.

Correct! Again, the ARRL Handbook said that covers are optional
but this morning at the beach I talked with an RF EE and he said
tuning is typically done capacitively via a screw through the top
cover. He drew several response curves in the sand showing the
difference between inductive and capacitance tuning. (It's amazing
what gets discussed on the beach here!)

>Why not take a break from looking for TV sets and start looking
>for discarded land mobile radios?

Haven't see any in the dumpsters, although I've found some discarded
maritime mobile transceivers at the harbor, but I promptly cleaned them
up and sold them. Besides, I'd rather build the resonators by hand.

>Hey, 147MHz? That's 2m. What are you doing on 2m?

Maybe I can get some Techs interested in HF CW!

1226. Helical Resonators - Round or square?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-01 00:00:00 UTC
From: jeffrey@math.hawaii.edu
Message-ID: <D6CHJp.4Iz@news.hawaii.edu>
Source record: 113631

I want to build a helical resonator with an Fo = 147 MHz. The ARRL Handbook gives the design criteria for both round and square resonators, with no comment as to which performs best. Since copper pipe is readily available from hardward stores I am considering the round design. Also, the nomograph gives the design data for round resonators.

Also, the covers are said to be optional.

Comments (with regard to round or square, and covers) are welcome!

Oh, I don't plan on silver plating the shield and coil - that's only supposed to increase the unloaded Q by 3%.

73 from Hawaii,
Jeff NH6IL

"unconditionally stable" means that a device won't oscillate with
any combination of input and output load impedances, provided there
is no external feedback.

EVERY amplifier that has positive power gain is capable of oscillation,
you just need the right feedback. A ground loop or a unsuitable
decoupling cap might be enough.

1230. Recruiting Elmers from the Internet

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-01 00:00:00 UTC
From: pschleck@gonix.com
Message-ID: <pschleck.796747779@gonix.com>
Source record: 113714
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.antenna,rec.radio.amateur.digital.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.policy,rec.radio.amateur.space

As readers of the rec.radio.amateur.* newsgroups are probably aware, I maintain a periodic information posting known as the Amateur Radio Elmers Resource Directory (aka the "Elmers List") which provides a list of net Elmers, indexed by topic, and their E-mail addresses. (For users of threaded newsreaders, this article is linked to the base article of the Directory itself).

As noted elsewhere, the Amateur Radio Elmers Resource Directory is 4 years old as of last month. In order to maintain its value to the net, I have strived to keep it accurate and up-to-date. In addition to reviewing the currency of the entire list every 2 years, I am constantly scouring the newsgroups for new Elmers to join the list.

There's always been an implicit invitation for any qualified person to join the list. However, since I've lost about 1/3 of the list due to attrition from my last biannual mass-ack (i.e., no response at their last-known E-mail addresses), felt the need to send out this explicit invitation. I'd like to replace the lost Elmers with new, motivated, quality Elmers from the net. Areas of expertise that are most desirable for the list right now include:

- Military Affiliate Radio System (MARS), particularly Army and Navy/Marine-Corps. MARS (as I currently don't have any MARS Elmers from those branches)
- Advanced homebrewing techniques (surface-mount, VLSI, DSP, spread-spectrum, etc.)
- TCP/IP Packet Radio and Gateways/Internetworking (particularly local IP coordinators and/or subnet managers/operators/leaders)
- Amateur Satellites/Space Operation (particularly Microsats and SAREX)
- Amateur-related Software for Unix/PC/Mac/Amiga/Psion/HP-95
- College Clubs and organizational guidance/strategies
- Boy Scout Amateur Radio Merit Badge Counselors
- Unix/Linux/X-Windows programming and configuration
- Amateur Radio Organizational Contacts (I am especially looking for contacts for the ARRL Field Organization, GRAPES, AMSAT, QCWA, QRP Int., NARA(?), QRZ, CSVHFS, LAMBDA, ARES, RACES, FEMA, any state OES or EMA, as well as any regional frequency coordinating body)
- Band, Mode or, Brand-specific equipment (actual manufacturer or dealer contacts would be quite welcome, as long as they reveal their affiliation and at least provide *some* free services)
- Maintainers of unique amateur-radio-related anonymous File Transfer Protocol (FTP) sites and World-Wide Web (WWW) Home Pages (as opposed to those that are substantially a rehash of, or pointers to,

existing sites).
- Maintainers of unique amateur-radio-related mailing lists
- Editors/contacts for amateur-radio-related publications

Although expertise in any other area would, of course, be welcome also.

I'd like to emphasize that participation is totally voluntary, with very minimal obligations (1 or 2 polite inquiries a month, if feedback from existing Elmers is any indication). If you find that it is too much work, you are welcome to bow out, no questions asked. In the 4 years I have managed the list, only a handful of Elmers explicitly resigned, and usually only because of severe professional or personal obligations, or their interests or expertise changed. You don't even need access to netnews, just a reliable E-mail address.

I've also attempted to seek out people on the net who I think would be good Elmers. If you've received a personal E-mail invitation from me, I urge you to give it serious consideration. The net would appreciate your volunteerism.

If you'd like to volunteer, or just discuss further what volunteering would involve or if your contribution would be desirable and fit within the Elmers List's mission and editorial policies, send me some E-mail to the Elmers list administrivia mailbox below (the default Reply-To: of this message; an autoreply daemon will respond with an acknowledgement message and I'll be in touch with you personally very soon).

1231. Pls help me find TIL306 & TIL308 LEDs

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-01 00:00:00 UTC
From: dgf@netcom.com
Message-ID: <dgfD6C05H.Hqz@netcom.com>
Source record: 113715

I'm trying to find a source for a couple of TIL308 and TIL306 7-segment LEDs. Both have integral 7-segment drivers; one has a counter/latch too. I've searched my catalogs to no luck. I think these are/were TI part numbers. Could anyone take a look at your catalogs & offer a source?

Thanks very much!

73 Dave WB0GAZ dgf@netcom.com

Nathan, a pair of 6146s will handle this nicely. Tubes remain the
easiest way to get high power and high gain in the same package.

>would like. Bob Liesenfeld WB0POQ

ARRL Radio Designer is indeed an excellent small signal circuit simulator and design *aid*, however, that may not be what John is looking for. He may be looking for a schematic capture program, which RD is not, or a board layout program, which RD also is not. Or he may be looking for a program that produces component values for a design, which RD also is not directly. Hayward's _Introduction to Radio Frequency Design_ includes some programs that directly calculate component values for some circuits (oscillators, filters, etc). I now consider Hayward's book an essential item, as well as Chris Boswick's _RF Circuit Design_, and a shelf full of other references.

Radio Designer is a very useful program, but we should be clear that it doesn't actually design circuits. It's more a replacement for a lot of cut and try on the bench. Programs like Tango are more traditional schematic capture and board layout programs. And Mathcad is a *very* useful design aid. I'd recomend Mathcad to anyone doing circuit design. I'd also recomend Radio Designer, and a schematic capture program, and a board layout program, etc. There isn't one package that meets all needs.

For learning electronic circuitry, however, there are a couple of electronic "lab" programs that are available that demonstrate electronic circuits in action in a graphic way. While useless for actual design, they are great teaching aids. This may actually be what John is seeking.

1235. Really good low noise 12V wall-transformer?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-02 00:00:00 UTC
From: hl1@hudson12.acpub.duke.edu
Message-ID: <3lkqmv$a9u@news.duke.edu>
Source record: 113636

After reading the really interesting and informative QST article this month, and being tired of
switching over to gell cells when I want to do some serious listening, I am wondering if someone
of the net can name a really well designed and low noise 12-16 Volt / .5 -2 amp wall transformer
type power supply that I can buy to supply my AR3000.

The unit I am using right now has four diodes in a bridge (I tried soldering .01 uf caps across
them to surpress the pn junction turn-on spike: more noise not less) and a 1000 mf 24V filter
cap. There is also a 5 megaohm resistor between negative DC and AC neutral (what is this for?)

Does Drake, Yaesu, Icom, etc make a really good unit that you could give a part # for?

1236. 220 amp schematics wanted

1/2 volt of audio on the Gunn Diode sounds like way too much.
It may be many many MHz wide (FM), and AMing too, or even going in and out of microwave oscillation. Do you have access to a spectrum analyser to see?

Do you know if the two units are on frequency - that is - 30 MHz apart? Can you hear anything when you tune one of the Gunn's frequency with no modulation on? I think you should.

I agree that there's so much signal, and that because it's so strongly modulated (maybe turning entirely on and off at 1000 Hz) that the detector diode is simply rectifying it and it's local oscillator (Gunn diode) doesn't have to be on.

I assume that these are Solfan units, or something like them?

I don't know how to design the circuit but you could get your beep perhaps by
taking one of those goofy gizmos that generate a beep or whatever they have at
novelity shops apart and working with it.

Hi Jim,
Amateurs are the only radio service entrusted to self-police
themselves. That means looking out for yourself and your fellow
hams. It's too bad you carry into the service an attitude of
mistaking someone with a friendly reminder as being `anally-challenged'
(whatever that means - seems many folks are fascinated with that
region of the body.)

None of us have all parts of the CFRs entirely memorized. With that in
mind, you shouldn't snap at someone who is only trying to keep you out
of trouble with the law.

73 from Hawaii,
Jeff NH6IL

From: stoskopf@ink.org
Message-ID: <3ll942$6k@ink3.ink.org>
Source record: 113649

Was working on a 1 GHz osc and tried to run through the design example on p. 338 and following in Liao, Microwave Circuit Analysis and Amplifier Design, Prentice-Hall 1987. Entered the example in a MathCad file and found that things really fell apart when the embedding element values in step 4 were calculated and that the final results were not anywhere near those in the finished example in the text. Wrote Prof Liao thru P-H and Fresno State with no reply.

Did check the original references and the equations are correct. Anyone got the new edition or have the same problem?

Thanks,

N0UU

This is Pin 1

With the notch to the left, Pin 1 is always on the botton left of a DIP
IC package.

Hi Jim,

Huh?
I've used Avantek, Mini-Circuits, Anaren, and Motorola amplifiers,
with leads in the air, wrapped all over, and NO oscillation. (10 Khz-1 Ghz)
Did you not pay attention to the power bypassing? (That is critical!)

I hold Ham night (Elmer Session) every Monday night at 7 PM, when your in
the area, stop by, say Hi.

I'll show you a few different projects with (Blush) terrible layouts.
And they work! Cold Fusion indeed! (Besides, you don't know that in say...
500 years those guys might have been on the right track after all!)

:)

Eimac (Varian) makes a series of planar triodes that are ggod for high power to 1500 MHz and beyond: YU-141 and YU-176. One of thes in an appropriate cavity should give you 10 dB of gain at 1296. The gain of these tubes goes up at low, so you may be able to do even better than that. I've built a two stage amplifeier at 425 MHz with the YU-176's that puts out 3o kW pulsed with 100 W of drive.

Before this gets out of hand...

Irradiated Poly Vinyl Chloride is an insulation applied to wire.
Then you heat it... and it shrinks!

No glow, (Sorry!)

Check out "Heat shrink tubing"

Hey Justin,
I think you need to post this in the CB group.
They all have "Roger Beeps". Several kids come over Monday nights,
(They are now hams, so I can't say who...) they can design a "Roger Beep"
with just one chip (555).

But then they are just no-clue techs.

If your still interested in cluttering up the air-waves with "Beeps",
send me E-Mail (sefranek@iii.net), and I'll ask one of the kids to
reply to you.

:)

Source record: 113576

I've just seen an advert for Mini-Circuits POS-xxx VCOs. They look
ideal for frequency synthesisers, especially as they have +7 dBm output,
and may therefore be connected directly to an MCL mixer. Has anyone got any
experience of them?

Leon

>>Also, the covers are said to be optional.

>I wouldn't omit the covers. The resonator is usually tuned with a
>very small amount of capacitance, without a cover it would be
>easy to detune your resonator.

If you make the square or round tubes long enough the cover will have
less effect to passband. Some years ago I built a three-resonator
helix for 144 MHz (or actually tunable from 144 to 174). The inside
diameter was in order of one or one and a half inch and the extra
length was one diameter in each end. The helices were tuned
with high-Q piston capacitors. I think there were no change in
the filter response with or without the covers.

It is possible that when there is no tuning capacitors involved the
helices could be more sensitive to covers - at least at the high-Z end.

I used well grounded covers to prevent any microwave pickup at
frequencies above the waveguide cutoff frq.

BTW... has anyone actually measured the change in Q due to
silver plating? ... according to old wife tales it should be only 3 per cent.

|
|73's, N3DQC

What you could probably do is to wire up a device to go between your
microphone and radio that would actually do the keying of the transmitter for
you. So, when you press the key on your mic to transmit it actually would
sense that and would perform that function through either a relay or a
transistor/solid-state-relay for you. Then when you
let off on the key, it would detect this and would hold the (relay) closed
for just a few moments longer- enough to generate a tone and mix that in with
your mic input to the radio. Without working this out in too much detail, (no
doubt there are probably more elegant ways to do this or improve upon it, etc.
-without a whole lot of thought), you could do most of this using a couple of
555 timer circuits. One used as an oscillator that would generate the tone
you would desire and another to generate the delay needed to continue keying
the transmitter momentarily when you let off of the key. A little bit of
logic circuitry might also be needed to switch in the tone onto your mic level
when you let off of the transmit button that could involve either a couple
digital gates or transistors, what ever you prefer.
This could indeed be a fun project to dabble in, and I would recommend
that if your are just starting out, that you invest in a "breadboard" from
radio shack (they're about $10-12) and a few of the "Engineers mini-notebooks"
that radio shack sells. In these you'll find cicuits to do what I just
mentioned (they are quite simple) and a little explanation on how they work
and what you might be able to do to manipulate them for your purposes. You'll
find in these little books lots of ideas and "small" circuits that you can
possibly peice together to do what you'd like to do and have fun learning in
the process. The breadboard isn't meant as a permanent solution for your
design (although it could be) but is a quick way to get your circuit up and
running in just a few minutes to try out your ideas. Good luck!

Hi the name is Glenn KE6HPZ I'm having problems with my FT-2400 changing frequency when I have my TNC KPC-3 run in the open sql mode. Just about each time the TNC causes my TNC to TX it will bump the VFO up 5 khz or the memory up one memory. The radio uses two wires going to the mike that change the VFO up or down. Those connections are not even connected to any wires on the pigtail. This sometimes happens when I have the sql set too low, also. Does anyone have any ideas how to cure the problem or what is causing the problem.
Thanks

Cross-posted to: rec.radio.amateur.homebrew,alt.religion.mormon

N7WS (n7ws@aol.com) wrote in rec.radio.amateur.homebrew:
: Why is this stuff appearing in a forum for radio amateurs? Sure some of
: you are hams, even one of my best friends, but I think it's in poor taste.
: Wes Stewart, N7WS
: n7ws@aol.com

There was a reason for the post appearing here. There are a number of FM stations around the US which carry the Conference as well as other LDS programming on a SCA channel. There are several people on the 'net' who would like to build such a circuit. There is no rec.radio.homebrew, however, this group probably has the expertise. It was not explained in the original posting that appeared here, but there are a number of folks interested, if anyone has a circuit or would like to Elmer someone in building an SCA reciever --- please post (or crosspost) to alt.religion.mormon

The orignal article did mention SCA and building your own circuit (or very similar).

: as advertised by the early full page ads. Haven't messed with them in
: several years now but when they first came out we bought several of the
: Mini-Circuits MAR experimenter's kits and found they ALL were quite
: touchy about PC layout. If the PC strips feeding input and output weren't
: pretty close to perfect they would oscillate like crazy; hardly
: "unconditionally stable". Of course I've noticed similar behavior with
: "unconditionally stable" op amps too. I think "Unconditionally stable"
: is sorta like cold fusion or anti-gravity... awfully difficult to find
: in real life.

The MAR devices are the same. Unconditionally stable means they
won't oscillate no matter what the input and output termination
impedances.

This assumes the absence of external feedback paths.

It also assumes very good grounding, though I've not noticed
any problem running the 20 mil thick leads straight down to
the ground plane with 56 mil thick FR-4 circuit board. But,
the new MGA 86576 MMIC is quite touchy about grounding,
according to the application notes. I handle the GaAs MMIC's
supposed problem by using 15 mil thick Teflon circuit board.

BTW, you can run a cascade of a MAR-7 and MAR-8 to get an
unconditionally stable very high gain amplifier. I normally
use small capacitors to reduce the low frequency gain of
this pair (10 pF).

I've been thinking about doing a similar project - so this thread has
been helpful. I also think that he is turning the diode on and off and
hearing the rectified signal on the receive side.

My quesion is how *do* you tell what frequency you are on? I have a
couple of what I think are Solfan units, and about the only thing I can
think of (other than the not so handy 15 Ghz counter) is to do the
"wireless leacher wire" thing. Move a flat plate back and forth in front
of the diode's output and look for changes in current. Does that work on
these things? Is it accurate enough for 30 mhz resolution? Or is there an
obvious way to set them on frequency that I am missing?

Source record: 113580

I'm finishing a 2-meter 4CX-350 amp that another fellow started; all it needs is the high voltage and screen supply, and TR switching. One goal is to keep cost down, so a microwave oven HV transformer will be used for the HV supply. It's output voltage is about right, and the duty cycle should be low enough to keep it nice and cool.

This leaves the issue of a 350-volt regulated screen supply. The ARRL handbook shows regulators using gaseous regulator tubes or several 56-volt 10-watt zener diodes in series. But 10-watt zeners are a bit pricey, and regulator tubes are probably up there, too.

Are there any cheaper ways to get a 350-volt regulated supply? How about using a string of 1/2 watt zeners to run a high-voltage pass transistor? Do HV integrated regulators exist? (Well, you never know...) Any ideas/suggestions are appreciated.

When is a "turn" not a turn? When it's a significant fraction of a wavelength long! The LF transformer analog then becomes completely invalid, and instead you have to analyse the circuit as two coupled transmission lines. You'll find that the coupling is quite loose, and that's how the impedance step-down is achieved.

Actually, hams don't analyse this kind of circuit (and I don't think professionals do either). They just throw it together and fiddle with the coupling loop length and layout until it works. Far from the coupling being excessive, the usual problem is in making it tight enough. There's also a lot of uncertainty about the effect of the loop "tuning" capacitor. When you turn the knob clockwise, are you increasing or decreasing the loading? Who the heck knows? As a result, many loop-coupled VHF/UHF PAs run seriously under-loaded and aren't anything like as linear as they could and should be.

Ever since reading about the K2RIW PA for 432MHz, I've always had good luck with capactive output coupling. Unlike loop coupling, you have a decent shot at understanding and designing what's required:

X_c = sqrt(R_l / Z_out), near enough

where R_l = V_dc^2 / (2 * P_out)
Z_out = 50 R, usually.

The tuning C is reduced to compensate for the parallel reactance
of the coupling C. (Again, who the heck knows what a loop is
doing to the effective tuning capacitance?)

You can still use capcitive coupling in push-pull 144MHz PA
circuits. Mount two identical coupling flappers on the same
shaft, each one coupling to the hot end of the line but 180deg out
of phase, and then combine the outputs in a half-wave coax balun.
The conventional tuning flapper is on the opposite side of the
line.

With capacitive coupling, increasing the loading capacitance(s)
will always give heavier loading - never any doubt about it -
and the whole thing tunes and loads like it's on 80m.

: these things? Is it accurate enough for 30 mhz resolution? Or is there an
: obvious way to set them on frequency that I am missing?

Without a counter I think the best way may be to use another known source. If one has an SRD or something similar to make the spectrum of a lower frequency source rich enough to copy that can also work. If you have something that can switch fast and generate 10 GHz energy, perhaps even a Schottkey diode, the 23rd harmonic of a 446 MHx FM transmitter is about the middle of the 10 GHz hamband. You may be able to generate a few microwatts that you can detect using it as a harmonic generator. However, I've found another way which is also useful at getting one close, though not as good as a counter.

It appears that most motion detector sources (like Solfans) are initially set pretty close to their allotted 10525 MHz spot when they are initially deployed. It also seems that in general they don't move all that much. A survey with a Gunn diode xcvr, a small horn and a spectrum analyzer for an IF receiver, from my office here at work found 4-5 door opener signals associated with doors in buildings on this campus. They were pretty tightly clustered.

If you live near an area that has public buildings or business with automatic door openers and can conveniently get close enough to one to generate a big enough IF signal to detect, you may be able to set your local source to be offset by a known IF offset below 10525 MHz. Using a commercial FM receiver or other vhf 'detector' for an IF receiver can get you down in the 10425 MHz region.

Once you have that, you can bootstrap other sources at home and perhaps come up with a 'local standard'. With an approriate IF receiver and two transceivers, you should be able to 'leapfrog' down the band and land within a few MHz of any spot the transceiver will tune in the 10,000-10,500 MHz hamband.

This technique may be a bit crude but it appears to work. I described it, along with a phaselocked 1010 MHz source and a harmonic mixer that would make an even better frequency meter for sources on the 10 GHz band, in a three part series in 1988 Ham Radio Magazine. The series presented a method of building a phaselocked transverter "stack" for all the amateur

microwave bands.

I hope this helps.

Lars,
Here in the States there are several companies that sell various
cellular phone antennas from yagis to magnetic mount mobile types.
You can build your own if you are good at making UHF/SHF antennas.
I don't know what frequencies are used in Australia, probably the same
as here. If so your antenna would have a center transmit frequency of
863.5 MHz +- 2MHz and a receive center frequency of 859.5 +- 2MHz.

Good Luck

Kevin

It won't be cheap to get the kind of screen voltage regulation you
really need for good linearity, and also to protect the tube against
excessive positive or negative screen currents, flashovers etc.

4CX250s and 350s are very, very sensitive to variations in screen voltage.
If the screen voltage is allowed to swing around in response to the SSB
drive cycle, distortion products increase rapidly. You need to think in
terms of regulating the voltage to +/- a few hundred millivolts, for
current swings of +25mA to -25mA per tube. That isn't easy.

Zeners are barely adequate, though your idea of using lower-wattage
parts with a high-voltage shunt transistor is a good start. VR tubes
aren't adequate - 50 years ago they were the best you could get,
but their voltage regulation is lousy compared with what a 4CX250/350
needs.

I don't much like the screen supply circuits published in the ARRL
Handbook over the past several years. In particular I don't like
using a screen fuse or a string of blocking diodes. The logic seems
to be that in a flashover, it's more important to protect the zeners
than it is to protect the tube and the 600V bypass capacitor in
that expensive socket. When the fuse blows or the diodes block out,
the tube is left to the mercy of the flashover, with nothing but a
VDR and a 50k resistor to protect it. That may be some designers'

order of protection priorities, but it certainly isn't mine.

The tube and its socket should come first, and in the event of a flashover the zeners are there to help protect the tube, and need to stay connected at all times - so no fuse or diodes. My experience has been that 10W zeners survive just fine when the tube is also protected by VDRs. A large electrolytic (eg 50uF) across the zener chain helps the dynamic voltage regulation and also helps take the sting out of any flashovers.

If the zeners are permanently connected, any negative screen current can flow back through them and voltage reulation is maintained. (The circuit using diodes becomes totally UNregulated for negative screen currents - a major no-no!) At the expense of increased dissipation in the zeners, you can also remove the 50k shunt resistor, and arrange to bleed that extra current through the zeners. Thsi will also improve voltage regulation by keeping the zener current more constant. Contrary to what the tube datasheets say, you don't need a bleed resistor from screen to ground if you already have zeners or some other voltage regulating device doing the same job.

For some years now I've been using a fully electronic screen regulator with built-in overcurrent protection that trips the PA to standby. Almost anything that can go wrong for a 4CX will result in abnormal screen current, so monitoring screen current can protect against a wide range of potential problems.

Circuits are in the VHF/UHF DX Book (see sig). They'll cost you something to build, but they're still cheaper than 4CX250s!

1292. HELP v/uhf PA tank operation

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-04 00:00:00 UTC
From: jbraks@csu.murdoch.edu.au
Message-ID: <3lq2e4INNib2@newsman.murdoch.edu.au>
Source record: 113593

A HF output tank from a valve amplifier usually uses a wound inductor and capacitor in different combinations, to couple the RF energy into the antenna. One of the simplest is a parallel combination of an inductor and capacitor for the tank circuit coupled to the antenna by a coil having less turns so that the 50 ohm antenna is transformed into the appropriate high value resistance for maximum power transfer.

My problem is that v/uhf circuits described in some articles use a resonant line as the tank circuit. For example, 2 tubes of a push/pull have their anodes connected by a rod shaped like a 'U', being connected at the start and end of the 'U'. The antenna is coupled by another 'U' loop (in series with a capacitor) which is placed in proximity to the PA 'U'. QUESTION how do you match the impedance of the antenna (50 ohms) the the high output impedance of the tubes (~1K). To me this seems like a 1:1 transformation since it looks like one turn couples to one turn.

Can someone please explain how this coupling technique really works ? No books that I have read seem to explain this and yet have heaps of similar circuits. Thanks.

Actually Tom they can be quite useful for ssb ms and aurora although ssb aurora will always be a poor second to cw.On 144 in Europe at meteor shower peaks a "roger beep" can be a Godsend amongst the cacophony of a good burst,it clearly indentifies that a station has finished transmitting and you can call him,providing of course you don't have a mouthful of coffee at the time!
So if used at appropriate times,carefully setup and with the addition of a bypass switch they do have their uses

Hi Jenn,
You can brute force jam count a 40161 to divide by 12.
Or use any other pre-settable binary counter.
If you need symetrical output, divide by 6 then by 2.

Several years ago someone in central Ohio was advertising a controller
that used the VIC-20/C-64. It used a plug-in card with the program on it;
I know a couple of people who are using them as controllers, and I have
one myself as a backup. I'll try and dig out the address for you.

1300. Very low freq./WWVB reciever

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-05 00:00:00 UTC
From: egrumling@aol.com
Message-ID: <3lv5dg$8lu@newsbf02.news.aol.com>
Source record: 113601

I'm wondering if anyone here knows anything about WWVB? This station sends time updates in a digital mode only (WWV uses a subcarrier of some sort to send digital), somewhere around 60KHz, I think. What I would like to do is build a reciever and just decode the signal into a display (to use as a UTC clock).

Any ideas...
E

1302. Info on Varian uwave tube?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-05 00:00:00 UTC
From: landisj@nad.com
Message-ID: <1995Apr5.195247.251@nad.com>
Source record: 113603

I picked up some kind of microwave source at a swap meet on Sun. By the size
of the waveguide, it looks like it's in the neighborhood of 10ghz. It has
a Varian tube(?) in it numbered VA-210C. It's mounted on a cavity that seems to
be tuned by a dc motor driven geartrain; looks like some kind of swept source.

Anybody have any info on this device?

>Jennifer Gilfillan
You can use a 74C92 (how convenient...).
This is a CMOS equivalent of the TTL 7492. Most of the 74XXX series chips
have a CMOS equivalent. Check the pinouts, they should be exactly the same.

It looks like the regulator needs to souce as well as sink current.
Sounds like that would eliminate zener diodes running a high-voltage
pass transistor. It would be OK as a current source, but wouldn't
the transistor's P-N junction prevent it from being a current sink?
How about one regulator to handle current to the screen, with a
second to handle current from the screen? The second regulator would
have to be set for a slightly higher voltage, but not too much more.

I recently purchased a used FT-11R (it's in the mail). I was wondering what the general consensus is on this particular HT? I know I should have asked this sooner. This is Yaesu's best selling 2 meter HT at this time.
All I know about the radio is that it is tiny and puts out 1.5 watts with the standard battery/ 5 watts with optional pack.
thanks

Everybody laugh;

I'm so used to using repeaters, that wwhen I get on HF, I will constantly sit and wait for the beep that never comes.

I've often thought that a little beep would be a nice idea, provided it doesn't get carried into the class of the Roger Beep on CB and drive everyone crazy.

Years ago when we all had separate receivers and transmitters, a beep on keyup was a common occurance, due to the lag in the relays....

Hi Fred,

Thanks for you input.

I've meet Bob of Engineering Consulting. I saw a great demo at his house
a couple of months ago. I love the system! I feel however, that his
pricing is a bit out dated. Bob designed the Comshack about 5 years ago.
At this time, his is not updated any of the products or developing any new
ideas.

This is why I thought I would try to do it own my own.

What feature are you using? ie...phone patch,HF remote,VHF remote,packet
control ect....

How do you like the product over all?

What would you change?

Thanks

John KN6LH

I use C-64's for repeater controllers and have for several years,
starting out with VIC 20's and eventually moving to the C-64 since
it has easier programming tools available. Contrary to popular
opinion the C64 can be quite reliable and rugged running 24 hours
a day 365 days a year IF (and ONLY if) you chuck the "stock"
Commodore power supply and replace it with either a homebrew or non-
Commodore built unit. Mine has been running steadily with no glitches
for 2.5 years now with no down time nor replacements.
I use the user port and the cassette port to provide COR sensing,
repeater PTT switching, timing, etc, and courtesy beeps and CW
command feedback signals are all generated by the C64.
At least a couple of commercial vendors provide repeater hardware and
software using the customer-supplied C64 for the CPU.
Engineering Consulting in CA, ads in 73 and QST monthly, is one.
The software I wrote uses the C64 along with a few switching
transistors, 1n914 diodes, as well as a simple external SS1202
touchtone decoder. My repeater / remote base controls the 220
repeater, programs an external IC2AT remote base for frequency, on/off,
as well as controlling a Collins HF380 HF remote base. Touchtone
commands control the volume of the courtesy and ID tones, CW speed,
various bell/whistle functions, length of squelch tail, etc, and is
modifiable for additional functions if you know your BASIC and have
a BLITZ! compiler for the 64. You can review the functions available
on it by viewing my home page: http://sst.lanl.gov/~jdport/
.. Look under the "REPEATERS" section.
I can provide a disk with the software and associated schematics for
$5 per copy. I'll have to dig around, I think I still have the early
repeater-only non-remote base versions I can give you for nothing if
you send me a formatted C64 disk.

I've had good results with the MAV-11 from MiniCircuits.
+17dBm out, +12 dB gain 1GHz b/w, +30dBm 3rd out int. (and 3.8dB noise)

There isn't an MAR-11 equivalent as far as I know.

I built on a copper ground plane, drill a hole for the mmic to sit in, and cut little pads for the input and output. Few turns on a ferrite bead and a .25W metal film resistor to feed power in, 1nF feedthrough to decouple. Stable so far :-) (This is in a tracking generator, MAV3->MAV3->MAV11, 0-300MHz, +10dBm out)

Jim again:
: It looks like the regulator needs to souce as well as sink current.
: Sounds like that would eliminate zener diodes running a high-voltage
: pass transistor.

Sorry, my fault for not explaining it more fully. Yes, the screens of 4CX250s and 350s source current as well as sinking it like most tetrodes do. In fact under optimum loading conditions it's normal for the screen to source 5-10mA per tube at the peak of the drive cycle.

Because of this bidirectional screen-current feature, you can't use a series regulator: it must be a SHUNT circuit. Let's talk in terms of zeners for simplicity - a 350V chain of zeners from screen-grid to ground, fed from a +400V supply via a current-limiting resistor.

When the tube draws positive screen current, less shunt current goes down the zener chain, so you need to set the current limiting resistor so that there's still some current flowing down through the zeners in order to maintain voltage regulation.

When the tube is sourcing negative screen current, it flows away down the zeners to ground, and the zeners still maintain voltage regulation. To do this, they need sufficient power rating and heat-sinking to handle the additional current. (You see the problem with the circuit that uses blocking diodes to prevent a flashover from blowing the zeners? That circuit has NO voltage regulation for negative screen current!)

What I'd thought you meant about a "pass" transistor was the shunt regulator that uses a high-voltage NPN transistor as the main shunt element, with the zener chain connected from collector to base (and a resistor from base to ground). With a little care in design, that will work better than a simple chain of high-wattage zeners, because the zeners in the transistor circuit experience much less current variation across the SSB drive cycle.

Regarding the VHF/UHF DX Book, this is almost an FAQ!

RSGB still have large stocks, and there will not be a new print run until those have been sold. ARRL ran out of stock some time ago, but will not order any more until there is a second printing...

Anybody, world-wide, can order from RSGB. They accept all major credit cards. Their phone number is +44 1707 659015, although fax is obviously cheaper and more accurate: +44 1707 645105.

The price is 18.00 pounds and I believe that airmail for a single copy is under 3.00 pounds. Currently 1 pound = about $1.60.

As far as I know, the exchange rates on credit card transactions are very fair and there is no transaction charge.

: "wireless leacher wire" thing. Move a flat plate back and forth in front
: of the diode's output and look for changes in current. Does that work on
: these things? Is it accurate enough for 30 mhz resolution? Or is there an
: obvious way to set them on frequency that I am missing?

A frequency counter is very expensive for microwave frequencies. A cheaper alternative is a WAVEMETER. These are commonly found at fleamarkets or electronic surplus dealers for $20 to $100. I have always seen them available at Dayton. They are simple to use and will get you within a MHz of your desired frequency. Any further accuracy is futile with these Solfan gunn sources.

A wavemeter consists of a suitable size waveguide, a bandreject "cavity", and a diode detector. You connect a sensitive voltmeter to the detector and position the wavemeter for a good deflection or meter reading. The cavity plunger is controlled by a micrometer. The plunger/micrometer is slowly tuned until a sharp "dip" is seen with the voltmeter. Once the voltmeter reading is accurately minimized, the micrometer indication is cross-referenced on a table for frequency. More sophisticated wavemeters do away with the micrometer and have a frequency scale instead. Yet other wavemeters use coaxial connectors instead of waveguide.

Coupling distance (hence isolation) from the wavemeter to source can be increased by adding a small horn to the wavemeter's waveguide. This is also perfect for measuring LO leakage at 11.5 GHz from a radar detector!

I have found the wavemeters to be ideal for spacing out IF's in a micro-wave tx/rx setup.

For others experimenting with the SOLFAN units... try refrigerating the Gunn source for five minutes. When you pull it out, hook it to a Spec'A and watch it goooooooooooo! I found 5 minutes in the cooler = 15 MHz of drift. It is like a train.... you wait for it at the crossing and watch it go by. Any suggestions for stabilizing the thing?

Enjoy!

From: raiar@vulcan.inlink.com
Message-ID: <3lvjm7$if7@thor.inlink.com>
Source record: 113526

I am going to assume that you are refering to the 4011B IC-CMOS
Quad 2-input NAND Gate, for my reply.

The pin numbering is counterclockwise, pin 1 is the first one that you come
to after the notch or dot.

This numbering system is typical for numeroous IC chips, but not all as
previously stated by another postee.

If the notch is at the top, pin 1 is top left and pin 14 is top right.

This particular chips Vdd is pin 14, topright, and can tolerate anywhere
from 3V to 15V.

Pin number 7 is your Vss or ground pin, bottom left pin.

>ideal for frequency synthesisers, especially as they have +7 dBm output,
>and may therefore be connected directly to an MCL mixer. Has anyone got
any
>experience of them?

I just received 5 POS-150's yesterday. They were rated from 75MHz to
150MHz. They certainly do that. The low end was 59MHz. I was unable to
measure greater than 150MHz with the analyzer I was using but it did meet
spec. The output power was only +4-5dBm over the band. Not quite +7 but
it was very flat. I would say they work quite well and at $12, they are a
steal.

>using a string of 1/2 watt zeners to run a high-voltage pass transistor?
>Do HV integrated regulators exist? (Well, you never know...) Any
>ideas/suggestions are appreciated.

>73...Jim N2VNO

Jim, I would use a shunt regulator. I use HV PNP transistors (you can
ground
the metal case) referenced by a zener diode circuit. This keeps the
current
in the zener fairly constant, and the transistor has the varying load. I
disagree a bit with the need for millivolts of regulation, two tone tests
here have never proven that to be required. Your exciter will be the
dirtiest
part of the system.

The shunt regulator can be powered through a large dropping resistor from
the
anode supply. With tubes like the 4CX5000 and up I use a CT on the HV
xfmr,
but with only a few kV you could use the full hv.

Adjust the dropping resistor for only enough standing current to
adequately
supply the tube during signal peaks, plus a slight margin. As long as the
supply voltage is twice (or greater) of the screen voltage, you will be
effectively current and screen dissipation limited by the dropping
resistor.

This circuit has several advantages. It will not allow application of
screen
v before anode v, it is a shunt regulator and prevents soaring screen v
from
negative current or an arc, it current limits, it is stable, and it is
simple. It does have the disadvantage of heat in the resistor.

If you do use a series regulator, include a shunt regulator set at
slightly
more than operating voltage.

Never ever never depend on fuses to protect a tube. They were build to stop
fires, not save grids.They are notoriously unreliable and very slow. Use electronic methods, like the large series impedance from the resistor or a properly designed trip circuit.

I also use a small electrolytic from the screen to ground to absorb transients. I would NEVER bother using a VDR. The barely drop in resistance
as the current increases, unless my catalogs are wrong! VDR's are great for
protecting telephone lines so that lightning doesn't arc through the insulation, but they are very very poor if transients need to be limited to
less than a few hundred percent of the operating voltage. Just look at the slow slope of the resistance vs voltage on any VDR.

FLEA all SUMMER at MIT
April 16th, 1995
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $2 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
tailgate area is available for all sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

From: wave@mindspring.com
Message-ID: <3lvs73$jvs@henri.mindspring.com>
Source record: 113617

I am working on an all band transverter and need a 45.75 MHz IF. I recently purchased an Alinco DR-M06 radio for this sole purpose and have not been able to locate the modification information for it. I was told from a very respectable source that the radio was capable of transmitting in this frequency with reduced output. I am willing to pay $30 for the modification information for this radio. The radio currently receives from 40 to 60 MHz after turning it on with the Call button pressed.

I recently received some e-mail from some guys in England explaining how to perform the mod. Unfortunately, the info was not specific enought on which pads needed to be jumpered. If you have any info I would really appreciate if you can get in touch with me via e-mail or this newsgroup.

Thanks

Well, it might be of use to put the drift in context first. The numbers don't appear to be quite so awful that way. 15 MHz for 20-30 degrees C change is on the order of what many microwave oscillators do. YIG tuned oscillators are often in this vicinity. Also, 15 MHz drift at 10500 MHz is comparable to 6 KHz drift at 4 MHz. Would your non-temperature compensated VFO design for a 75 meter rig be all that much more stable if you put it into the cooler for the same length of time? Perhaps a bit but probably not a lot.

Still, for medium to narrowband use, 15 MHz is a lot. Why don't you consider phaselocking the Solfan if you want it not to drift? I show all the necessary circuits to make a 10 GHz SSB station in Feb/Jun/Oct 1988 Ham Radio Magazine. The microwave oscillator used is none other than a phaselocked Solfan source with bias push tuning. Also shown is the resultant phase noise. It's not as good as the best one can do but it's very acceptable even for very narrowband work; SSB and CW. This is the same hardware architecture I used when we originally pushed the long standing 200+ mile 10 GHz over-land record out to 400+ miles.

>do not want to have to mortgage my home for the parts!!

If you don't require a solid-state solution, there are plenty of articles
and designs for just what you want in older handbooks.

Any of the following tube combinations will give you what you want:

(1) 813 (drive in grounded grid or grid-drive -- driving the grid
will give you something like 25W in, 400W out on SSB.)

(2) 811's same deal as above; best in grounded-grid

(1) 4x250

(1) 3-500 grounded grid

There are several other designs. 813's used to be cheap in used markets, I
don't know how they are now. 811's are certainly still around. 3-500's are
certainly around, but they get expensive.

for solid-state stuff, I expect you're going to have to cough up more cash
for parts.

1335. 200MHz IF

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-07 00:00:00 UTC
From: mikael.landing@teknikum.uu.se
Message-ID: <3m2oto$1852@columba.udac.uu.se>
Source record: 113536

Planning to build a receiver for 1.75GHz (DCS-1800).
Have found out that a suitable IF would be 201MHz. Since I only
want one IF there must be alot of amplification on 201MHz (90dB).
Still I cant accept any limiting (must be linear gain).

Does anyone know how this could be done in a simple way. If I choosed
a lower IF I could buy some IC making the job. But I havent
been able to find any IC doing the job at 201MHz.

Maybee you know of some suitable device or solution?

Thankful for help!

Micke

1337. B&W corporate suicide?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-08 00:00:00 UTC
From: wrt@eskimo.com
Message-ID: <D6pLM6.46J@eskimo.com>
Source record: 113538

What has happened to the fine old Barker and Williamson company? Are they trying to kill themselves?

I went into the local ham emporium to buy some miniductor coil stock and was surprised to hear they no longer stock it. The manager told me that B&W now has a $2000 minimum order policy and at that price, they're not interested. Who could blame them?

I then called around to several of the advertisers in QST. Nobody stocks miniductor coils anymore.

I then called the factory. A bored-sounding clerk droid said yeah, they still make the 3033 I wanted, but there was none in stock. If I wanted one, it would be $17-something plus a $50 setup fee!!!

Question: what kind of company charges a setup fee for a product which should be in stock and readily available?

Answer: a soon-to-be-nonexistent one!

I'm really sorry to see B&W do this to themselves. I've been using their products since back in the '50s, and they will be missed. Their current attitude will not.

Anyone know of a source for 3033 coil stock?

Thanks, Bill W7LZP

wrt@eskimo.com

P.S. to add insult to injury, the clerk droid told me that B&W had bought out AIRDUX - their only competition - several years ago. :-(

: "wireless leacher wire" thing. Move a flat plate back and forth in front
: of the diode's output and look for changes in current. Does that work on
: these things? Is it accurate enough for 30 mhz resolution? Or is there an
: obvious way to set them on frequency that I am missing?

A frequency counter is very expensive for microwave frequencies. A cheaper
alternative is a WAVEMETER. These are commonly found at fleamarkets or
electronic surplus dealers for $20 to $100. I have always seen them
available at Dayton. They are simple to use and will get you within a
MHz of your desired frequency. Any further accuracy is futile with these
Solfan gunn sources.

A wavemeter consists of a suitable size waveguide, a bandreject "cavity",
and a diode detector. You connect a sensitive voltmeter to the detector
and position the wavemeter for a good deflection or meter reading. The
cavity plunger is controlled by a micrometer. The plunger/micrometer is
slowly tuned until a sharp "dip" is seen with the voltmeter. Once the
voltmeter reading is accurately minimized, the micrometer indication is
cross-referenced on a table for frequency. More sophisticated wavemeters
do away with the micrometer and have a frequency scale instead. Yet other
wavemeters use coaxial connectors instead of waveguide.

Coupling distance (hence isolation) from the wavemeter to source can be
increased by adding a small horn to the wavemeter's waveguide. This is
also perfect for measuring LO leakage at 11.5 GHz from a radar detector!

I have found the wavemeters to be ideal for spacing out IF's in a micro-
wave tx/rx setup.

For others experimenting with the SOLFAN units... try refrigerating the Gunn source for five minutes. When you pull it out, hook it to a Spec'A and watch it gooooooooooooo! I found 5 minutes in the cooler = 15 MHz of drift. It is like a train.... you wait for it at the crossing and watch it go by. Any suggestions for stabilizing the thing?

Enjoy!

From: mikael.landing@teknikum.uu.se
Subject: 200MHz IF

Planning to build a receiver for 1.75GHz (DCS-1800).
Have found out that a suitable IF would be 201MHz. Since I only
want one IF there must be alot of amplification on 201MHz (90dB).
Still I cant accept any limiting (must be linear gain).

Does anyone know how this could be done in a simple way. If I choosed
a lower IF I could buy some IC making the job. But I havent
been able to find any IC doing the job at 201MHz.

Maybee you know of some suitable device or solution?

Thankful for help!

Micke

Before this gets out of hand...

Irradiated Poly Vinyl Chloride is an insulation applied to wire.
Then you heat it... and it shrinks!

No glow, (Sorry!)

Check out "Heat shrink tubing"

N7WS (n7ws@aol.com) wrote in rec.radio.amateur.homebrew:
: Why is this stuff appearing in a forum for radio amateurs? Sure some of
: you are hams, even one of my best friends, but I think it's in poor taste.
: Wes Stewart, N7WS
: n7ws@aol.com

There was a reason for the post appearing here. There are a number of
FM stations around the US which carry the Conference as well as other
LDS programming on a SCA channel. There are several people on the
'net' who would like to build such a circuit. There is no
rec.radio.homebrew, however, this group probably has the expertise. It
was not explained in the original posting that appeared here, but there
are a number of folks interested, if anyone has a circuit or would like
to Elmer someone in building an SCA reciever --- please post (or
crosspost) to alt.religion.mormon

The orignal article did mention SCA and building your own circuit
(or very similar).

Subject: Need TX mod info for Alinco DR-M06 6 meter Will Pay $30.

I am working on an all band transverter and need a 45.75 MHz IF. I
recently purchased an Alinco DR-M06 radio for this sole purpose and have
not been able to locate the modification information for it. I was told
from a very respectable source that the radio was capable of transmitting
in this frequency with reduced output. I am willing to pay $30 for the
modification information for this radio. The radio currently receives from
40 to 60 MHz after turning it on with the Call button pressed.

I recently received some e-mail from some guys in England explaining how to perform the mod. Unfortunately, the info was not specific enought on which pads needed to be jumpered. If you have any info I would really appreciate if you can get in touch with me via e-mail or this newsgroup.

Thanks

Subject: Where is pin 1 on the 4011 chip?

I am going to assume that you are refering to the 4011B IC-CMOS Quad 2-input NAND Gate, for my reply.

The pin numbering is counterclockwise, pin 1 is the first one that you come to after the notch or dot.

This numbering system is typical for numeroous IC chips, but not all as previously stated by another postee.

If the notch is at the top, pin 1 is top left and pin 14 is top right.

This particular chips Vdd is pin 14, topright, and can tolerate anywhere from 3V to 15V.

Pin number 7 is your Vss or ground pin, bottom left pin.

Gary

Hi Jim,

Huh?
I've used Avantek, Mini-Circuits, Anaren, and Motorola amplifiers,
with leads in the air, wrapped all over, and NO oscillation. (10 Khz-1 Ghz)
Did you not pay attention to the power bypassing? (That is critical!)

I hold Ham night (Elmer Session) every Monday night at 7 PM, when your in
the area, stop by, say Hi.

I'll show you a few different projects with (Blush) terrible layouts.
And they work! Cold Fusion indeed! (Besides, you don't know that in say...
500 years those guys might have been on the right track after all!)

:)

There is a company called FAR Circuits which makes circuit boards for a variety of projects. One is called the The Most Accurate Frequency Standard which is from January, February, and March, 1994, 73 magazine. It uses WWVB transmissions to make a very accurate standard.

The address is:

FAR Circuits
18N640 Field Court
Dundee,
Illinois 60118

Also, Ham Radio mag described a similar project back in the 1980's.

1345. Re: Q: Regulated screen supply

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-09 00:00:00 UTC
From: wrt@eskimo.com
Message-ID: <D6qxr7.JB@eskimo.com>
Source record: 113546

Here's the text of the screen-grid operation section in the 4CX1000A data sheet. It applies to most if not all of the various tubes mentioned in this thread:

"Screen-Grid Operation - Tetrode tubes may exhibit reversed screen current to a greater or lesser degree depending on individual tube design. This characteristic is prominent in the 4CX1000A and, under some operating conditions, indicated negative screen currents in the order of 25 milliamperes may be encountered.
The maximum rated power dissipation for the screen grid in the 4CX1000A is 12 watts and the screen power should be kept below this level. The product of the peak screen voltage and the indicated dc screen current approximates the screen input power except when the screen current indication is near zero or negative. In the usual tetrode amplifier, where no signal voltage appears between cathode and screen, the peak screen voltage is equal to the dc screen voltage. Experience has shown that the screen will operate within the limits established for this tube if the inidcated screen current, plate voltage and drive voltage approximate the 'Typical Operation' values.
The screen supply voltage must be maintained constant for any values of negative and positive screen currents that may be encountered. Dangerously high plate currents may flow if the screen power supply exhibits a rising voltage characteristic with negative screen current. Stabilization may be accomplished in several different ways. A bleeder resistor may be connected from screen to cathode; a combination of VR tubes may be connected from screen to cathode; or an electron-tube regulator circuit may be used in the screen supply. It is absolutely essential to use a bleeder if a series electron-tube regulator regulator is employed. The screen bleeder current should approximate 70 milliamperes to adequately stabilize the screen voltage. It should be observed that this bleeder power may be usefully employed to energize low-power stages of the transmitter."

Of course, where it says "electron-tube" or "VR", you may substitute an appropriate solid state equivalent.

I'm in the process of building an amp using the 4CX1000A and have chosen to go with the bleeder resistor by itself for reasons of simplicity and reliability. How well it works.... we'll see.

Hi De N3GLV in Pittsburgh,
I have come across a Nutec 16 channel VHF mobile at a nice price.
It is all on 151mhz now and appears to be programmed by a 2716 Eprom.
I have dumped the contents of the ROM to no avail.
I need programming info to set it up for 144-147mhz packet simplex.
I also want to add another 'bank' of 16 memories via a switch on one of
the un-used address pins. The service manual I saw indicated that tihs was possible.
ble.
Does anyone know where I can get the software nesecarry to set-up ROM mask?
Or if not the actuall software, can I get you to send me a mask to burn?
Thanks in advance for any info.

electronic surplus dealers for $20 to $100. I have always seen them
available at Dayton. They are simple to use and will get you within a
MHz of your desired frequency. Any further accuracy is futile with these
Solfan gunn sources.

A wavemeter consists of a suitable size waveguide, a bandreject "cavity",
and a diode detector. You connect a sensitive voltmeter to the detector
and position the wavemeter for a good deflection or meter reading. The
cavity plunger is controlled by a micrometer. The plunger/micrometer is
slowly tuned until a sharp "dip" is seen with the voltmeter. Once the
voltmeter reading is accurately minimized, the micrometer indication is
cross-referenced on a table for frequency. More sophisticated wavemeters
do away with the micrometer and have a frequency scale instead. Yet other
wavemeters use coaxial connectors instead of waveguide.

Coupling distance (hence isolation) from the wavemeter to source can be
increased by adding a small horn to the wavemeter's waveguide. This is
also perfect for measuring LO leakage at 11.5 GHz from a radar detector!

I have found the wavemeters to be ideal for spacing out IF's in a micro-
wave tx/rx setup.

For others experimenting with the SOLFAN units... try refrigerating the Gunn source for five minutes. When you pull it out, hook it to a Spec'A and watch it gooooooooooooo! I found 5 minutes in the cooler = 15 MHz of drift. It is like a train.... you wait for it at the crossing and watch it go by. Any suggestions for stabilizing the thing?

Enjoy!

Subject: 200MHz IF

Planning to build a receiver for 1.75GHz (DCS-1800).
Have found out that a suitable IF would be 201MHz. Since I only
want one IF there must be alot of amplification on 201MHz (90dB).
Still I cant accept any limiting (must be linear gain).

Does anyone know how this could be done in a simple way. If I choosed
a lower IF I could buy some IC making the job. But I havent
been able to find any IC doing the job at 201MHz.

Maybee you know of some suitable device or solution?

Thankful for help!

Micke

Subject: Irradiated Wire ??

Before this gets out of hand...

Irradiated Poly Vinyl Chloride is an insulation applied to wire.
Then you heat it... and it shrinks!

No glow, (Sorry!)

Check out "Heat shrink tubing"

: Why is this stuff appearing in a forum for radio amateurs? Sure some of
: you are hams, even one of my best friends, but I think it's in poor taste.
: Wes Stewart, N7WS
: n7ws@aol.com

There was a reason for the post appearing here. There are a number of
FM stations around the US which carry the Conference as well as other
LDS programming on a SCA channel. There are several people on the
'net' who would like to build such a circuit. There is no
rec.radio.homebrew, however, this group probably has the expertise. It
was not explained in the original posting that appeared here, but there
are a number of folks interested, if anyone has a circuit or would like
to Elmer someone in building an SCA reciever --- please post (or
crosspost) to alt.religion.mormon

The orignal article did mention SCA and building your own circuit
(or very similar).

From: wave@mindspring.com (Pieter Ibelings)
Subject: Need TX mod info for Alinco DR-M06 6 meter Will Pay $30.

I am working on an all band transverter and need a 45.75 MHz IF. I
recently purchased an Alinco DR-M06 radio for this sole purpose and have
not been able to locate the modification information for it. I was told
from a very respectable source that the radio was capable of transmitting
in this frequency with reduced output. I am willing to pay $30 for the
modification information for this radio. The radio currently receives from
40 to 60 MHz after turning it on with the Call button pressed.

I recently received some e-mail from some guys in England explaining how to perform the mod. Unfortunately, the info was not specific enought on which pads needed to be jumpered. If you have any info I would really appreciate if you can get in touch with me via e-mail or this newsgroup.

Thanks

Subject: Where is pin 1 on the 4011 chip?

I am going to assume that you are refering to the 4011B IC-CMOS Quad 2-input NAND Gate, for my reply.

The pin numbering is counterclockwise, pin 1 is the first one that you come to after the notch or dot.

This numbering system is typical for numeroous IC chips, but not all as previously stated by another postee.

If the notch is at the top, pin 1 is top left and pin 14 is top right.

This particular chips Vdd is pin 14, topright, and can tolerate anywhere from 3V to 15V.

Pin number 7 is your Vss or ground pin, bottom left pin.

Gary

>100W in and give me 300 to 500 out? I would like to build one but
>do not want to have to mortgage my home for the parts!!

If you don't require a solid-state solution, there are plenty of articles
and designs for just what you want in older handbooks.

Any of the following tube combinations will give you what you want:

(1) 813 (drive in grounded grid or grid-drive -- driving the grid
will give you something like 25W in, 400W out on SSB.)

(2) 811's same deal as above; best in grounded-grid

(1) 4x250

(1) 3-500 grounded grid

There are several other designs. 813's used to be cheap in used markets, I
don't know how they are now. 811's are certainly still around. 3-500's are
certainly around, but they get expensive.

for solid-state stuff, I expect you're going to have to cough up more cash
for parts.

Subject: Schematic for Power Designs 1543A 10 kV power supply needed

I urgently need a copy of the schematic for a Pwer Designs model 1543A 10 kV, 5 mA power supply.
Thi s is a fairly old unit that uses a 4-65 as a series pass regulator. The control electronics
has a 702 op amp and a few transistors. Apparently the control section is no functioning. There
is voltage at the anode of the 4-65 but 0 at the output. I will pay for FAX or shipping costs.

Bill, you gotta realize that almost NO ONE is buying AIRDUX
and MINIDUCTORS these days! With the advent of chips etc.,
you are asking someone to re-tool and BUILD you parts for
40-50 year old technology! Of course they have to charge!

Imagine if you wanted to got out and buy ONE brand new 1957 Chevvy
and asked GM to re-tool and make you one, just one from scratch!

BT>What has happened to the fine old Barker and Williamson company? Are
BT>they trying to kill themselves?

BT>I went into the local ham emporium to buy some miniductor coil stock and
BT>was surprised to hear they no longer stock it. The manager told me that
BT>B&W now has a $2000 minimum order policy and at that price, they're not
BT>interested. Who could blame them?

BT>I then called around to several of the advertisers in QST. Nobody stocks
BT>miniductor coils anymore.

BT>I then called the factory. A bored-sounding clerk droid said yeah, they
BT>still make the 3033 I wanted, but there was none in stock. If I wanted
BT>one, it would be $17-something plus a $50 setup fee!!!

BT>Question: what kind of company charges a setup fee for a product which
BT>should be in stock and readily available?

BT>Answer: a soon-to-be-nonexistent one!

BT>I'm really sorry to see B&W do this to themselves. I've been using their
BT>products since back in the '50s, and they will be missed. Their current
BT>attitude will not.

BT>Anyone know of a source for 3033 coil stock?

BT>Thanks, Bill W7LZP

BT>wrt@eskimo.com

BT>P.S. to add insult to injury, the clerk droid told me that B&W had bought
BT>out AIRDUX - their only competition - several years ago. :-(

I am looking for infor on HF power transitor labeled as:

TRW PT 9780
7823

Four of them are used in a short-lot 500W HF power amplifier from RF Labs. By the way, the amplifier needs increasingly more power on higher bands. For full output it needs 5W on 160m to 100W on 13m, and it produces only 200W on 10m. This could be related to the design, not the transistors.

>JE>>What has happened to the fine old Barker and Williamson company? Are
>JE>>they trying to kill themselves?

No, it's the unfortunate facts of the modern marketplace. It costs money
to keep old components in stock (and you can thank Reagan's tax reform for
that), and so it's just no longer profitable for manufacturers to keep
around parts that don't sell in large quantities.

I don't like it either. But I have found a solution. I wind my own coils.
This is rec.radio.amateur.homebrew after all. It's not half as bad
as making up your own capacitors or resistors (both of which are a lot of
fun too).

The MRF464 is listed as a direct replacement for the PT9780 in the
Motorola Semiconductor Cross reference. I assume you have access to a
Motorola data book if not let me know.
The PT9780 is a 28 volt 1.5 to 30 MHz device rated for 100W with 14db
power of gain.
Hope this helps.

Inductors on chips? Never heard nor seen that. Inductors
will always be needed by the homebuilder. One can either
wind on an air-core form or on a toroid.

L = (ND)^2 / (18D + 40S) for air-core coils, where

L = inductance (in uH), N = number of turns, D = diameter,
and S = length (all in inches).

Hello N3GLV

N6SLD here. If you have a service manual for the Neutec the info you are after is in the manual. I'm assuming that it is a SM-1645H model. The manual contains a method for you to calculate the data to put the reciever and transmitter on the frequency of your choice. Once you calculate the data you can enter it in hex with almost any eprom programer. You will most likely have to adjust the transmit and receive VCO's to get it to work. Also some minor retuining of the transmitter finals and the receiver front end may be required. In any case it's all in the manual. I have three of these radios in service for use on two meters. If you need more help you can reach me the fastest at lothringer#d#roy@ssdgwy.mdc.com as I only look over here once in a while.

Some of the best air variable capacitors ever made were in the old WWII command radio transmitters. They had ball bearings at both ends of the shaft, a beautiful gear reduction drive and they were built like a tank. Best of all, there are still lots of them around if you can find them. Flea markets are a good place to look.

Good luck!

Hey guys try this one. Take a threaded bolt or a threaded piece of PVC.
You can find it at local plumbing supply.
wind your wire in the threads and then use hot melt glue draw a line of it down
four side lt it cool down and then unscrew it from the form.
You can get threaded pvc from 1/2"-8" really easy. it goes bigger but *what
would you wind it for* =Kaliforna kilo'watt HIHI

1386. XR 083 Dual Bifet Opamp data?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-12 00:00:00 UTC
From: raateland@vyh.fi
Message-ID: <1995Apr12.092028@vyh.fi>
Source record: 113487

I picked up some Dual Bifet OpAmps XR083, but I can't find any data on them. 081, 082 and 084, yes, but 083, no.

My guess is they are not compensated and that's why they're not among the more popular items that you can find in e.g. the ARRL Handbook. Does somebody on this list know more about these? I would use the critters as a substitute for the above-mentioned types if possible.

thanks,

For all you microwave experimenters out there, I have for sale a Systron Donner model 1618 synthesizer, 2 - 18 Ghz in 1 Khz steps. The unit has an internal oven oscillator with stability of about in 10e-8/day, and all functions can be controlled from the front panel or via IEEE-488. Output level is from -110 dbm to +10 dbm. Frequency and amplitude are shown on LED readouts. This unit is also capable of AM and FM modulation via external inputs.

The unit is in good working condition, with the exception of normal wear and tear on the exterior. Manual included.

Asking $1500

1392. antenna switch

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-12 00:00:00 UTC
From: sbertsch@magnus.acs.ohio-state.edu
Message-ID: <3mhj12$8cj@charm.magnus.acs.ohio-state.edu>
Source record: 113493

I'm thinking of building a coax switch to connect my 2M allmode to either a vertical or horizontal antenna. I was thinking of using a 2 pole, 2 pos. wafer to switch both the inner conductor *and* braid, so as to completely disconnect the unselected feedline. My question is: will the wafer switch and short coax pigtails soldered to it introduce an unacceptable impedance bump at 144 MHz, or will the effect be negligible?

Steve

1393. Can anyone tell me how to build a CB antenna?

1394. Need Help solving TS850S RF Feedback problem.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-12 00:00:00 UTC
From: wave@mindspring.com
Message-ID: <3mhnus$122@henri.mindspring.com>
Source record: 113495

I have a Kenwood TS-850S radio that seems to have an RF Feedback problem. Whenever I have the processor ON, I cannot increase the mic gain higher that 4. I have tried connecting the radio to a dummy load and a 13.8V battery and the problem is still present. The problem is still present without a microphone and with the monitor turned off.

The problem seems to be internal and not related to rf feedback caused by rf on the shield of the coax since it is doing it with a dummyload. Could this be a problem with RF bypassing inside the radio probably in one of the mig gain stages?

IF you have any suggestions or have seen the problem before, I would appreciate any help. This is a recent problem. I've had the radio for one year and never noticed it.

thanks...

To Bill, W7LZP and all,

You can thank the US Tax laws which penalize companies who produce enough materials to place some in inventory for future sales. Write your congressman/woman/senitor and tell them to lighten-up on business. While you're at it; tell them do dump NAFTA and bring the jobs back to America.

In the meantime, get a good list of hamfests and get there early. There is always someone with coil stock (new and used) for sale. Also, you could try to wind your own, it's not that hard. First determine the diameter and wire size and spacing. Find a non conductive / non inductive coil form (plastic tubing works good, as does dry wooden dowels, coated with varnish.) Also find some string the size of the spacing between the turns. Then carefully drill a small hole in the coilform, near one end. Determine the length desired and drill the other end at the same time. Taking one end of the wire, push several inches through the hole from the outside towards the inside and then bend the wire 90 degrees (to hold it in place.) Take the string and wind the coil with the wire spaced with the string, until you get to the other end. ie: wire-string-wire-string-wire-string etc. When you reach the other end, pass the wire through that hole and bend that end 90 degrees. Make sure the wire is wound tight on the form. You're done. You can also coat the coil with more varnish if desired. Don't coat the wire where you intend soldering.

Help...
I have just acquired a Teletype Perforator/Transmitter, Model TT56/MGC.
The Unit Was made by Baker and Williamson, for the Signal Corps.

I Operate a Antique Radio Museum in Bellingham Washington, and wish to
use the unit for a working display... now the problem:

The units' motor works, and all appears to be in good working condition
except for the fact that the unit seems to be locked into repeating a
single keystroke over and over with each cycle. There is a small relay top
towards the rear which when closed causes this repeating to stop. Also
when I type on the keyboard, none of the keys engage, or type.
Does anyone have any information on this unit? I would like to get a
service manual or copy of one.
Anyone interested in the Museum site can check out what I am doing at:
http://olympic.pacificrim.net/~radio
Any help with this project will be greatly appreciated.
And Thank you!
Jonathan Winter

1397. Review of world's first superhet. in Wireless World

I learned about this from a publisher, Krieger books here in Melbourne, and they implied that the decision was a mid-80's thing. The tool company had a lot of old hammers on hand, and declared them at some depreciated value while they took up floor space. The IRS ruling was that they had to carry full list price for anything in inventory.

Although the IRS probably didn't think of such things, or doesn't care, it hit the publishers very hard. Tech publishers, especially, will load up a pallet with a "standard text" knowing that someday they'll sell them. Now that they have to declare full price on them, and pay taxes on that price, the number of titles available has dropped like a rock. It has also given rise to the book surplus market, which clears out last year's best sellers for pretty big discounts. Overall, though, the effect has been bad.

FWIW,
Bob

1399. Making Air-Dux/B&W style coils at home

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-13 00:00:00 UTC
From: d.diamond@trl.oz.au
Message-ID: <d.diamond.193.000C6F2F@trl.oz.au>
Source record: 113500

MAKING AIR-WOUND COILS FOR HF
from Drew, VK3XU (text only, no photo's). For possible interest:

We have all admired those photographs of antenna couplers and power amplifiers with Air-Dux (TM) or B&W (TM) air-wound coils. By using the minimum amount of former for support material, they look, and are, efficient. Not many years ago, we could order Australian made equivalents from the William Willis Co., but sadly, no longer trading. At time of writing, there is no known local supplier. They may be ordered from overseas, although the landed cost can be rather high.

For larger coils of perhaps 10 turns of 12 gauge wire, a perspex rectangle may be drilled with the number of holes necessary to accommodate the helix. The coil is wound onto a slightly undersized mandrel, then removed, and threaded or 'screwed' onto the former when a larger inductance involving tens of turns of smaller gauge wire is required, this technique is rather awkward and time consuming, and the results are not always as good as one would wish.

Here is a method that allows the home brewer to fabricate high-Q coils to requirements. The coil is supported upon a rectangle of perspex, or other low-loss material, such as fibre-glass circuit board- copper removed. Rather than have the turns running through holes, they are fixed upon a rack or comb cut along each edge of the former. In the example shown, we make a near equivalent to the B&W type 3022, which is a 20 uH coil of 40 turns of number 16 B&S, 8 turns per inch, 1.75 inches diameter. A template is recommended if you plan to make more than one coil of a specific diameter. Use brass sheet if you can get it, otherwise steel, about 18 gauge. Carefully, and as accurately as you can, mark out the cutting points for the two racks. A black felt-tip pen makes a good background medium for marking out. Remember to offset one rack by exactly one half of the pitch. In this example the pitch is 8 t.p.i., so the offset must be 1/16".

A hack-saw frame fitted with one or two blades, according to wire size, or better still, an Abrafile rod-saw (available from engineer's tool suppliers, comes with three blades and clips to suit an ordinary hacksaw) may be used to cut the rack. Take your time, and cut each slot to exactly the same depth, as evenly space d as possible. Clean up burrs with a smooth file. Cut a rectangle of perspex to size, then sandwich perspex and template together. Fix in place with two small G-clamps (cramps?). Mount the work in a vice, and

carefully cut each rack into the perspex.

Cut a length of suitably sized quad timber (90 degrees worth of round stuff) into four equal pieces, slightly longer than the plan ned coil length. Plane a small bevel along each edge. From thin plywood, make a pair of spacers to fit between the quads. The spacers should be about an inch longer to provide a 'handle' and so allow you to remove them when the coil is wound. Rub a little linseed oil into these parts to make them more slippery.

When you are ready to wind the coil, position the four quads and their spacers onto the perspex former, then temporarily wrap a length of tape around the assembly to hold the job intact, in order to receive the coil. Roughly calculate the length of wire required. In the example above it will be pi times the coil diameter times the number of turns; 3.14 X 1.75 X 40 = 220 inches. Unwind say, 240 inches (20') of wire and clamp the spool in in your vice. With a suitable tool, grip the far end of the wire and give it a firm stretch to remove any small wrinkles. The ends of the winding must be anchored by passing the wire through a hole or simply by bending the wire into a U, and seating it firmly down into a spare tooth for the purpose. Whilst maintaining tension on the wire, wind the coil onto the former by walking towards the vice. Remember to observe the winding sense. Make sure the wire seats nicely down into each tooth of the rack. When a few turns have been wound on, you can remove the tape; and complete the winding. Apply a narrow fillet of epoxy glue along the two racks to cement the winding in position. Take care that no glue finds its way onto the quad (the bevel on each of the quads should dodge this problem). Immediately hang the assembly in the vertical position. Finally, when the glue has set, grip the spacers in a vice and carefully pull one out, then the other.

If taps are required, form a spade on the tapping wire by flattening the end with a hammer. With pointed long-nose pliers, bend a loop in the spade to match the coil wire diameter. The wire may now be hooked and soldered onto the coil at the requisite spot without risk of shorting adjacent turns (Ref. 2).

The enamelled wire coil shown in the example has a measured Q of 350 at the 2.5 MHz test frequency. Unless it is done properly, silver plating the coil wire has little benefit, and may actually increase coil losses (Ref 3). Plain, enamelled or tinned copper is entirely satisfactory for amateur applications. Wire of 12, 16 or 18 B&S may be obtained from wire & insulation merchants, auto electricians and some electronics suppliers. Ordinary single-strand electrician's wire, stripped of insulation, or 'junked-but-good' power transformers are also a good source.

1402. FT-726R Hang AGC Mod

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-13 00:00:00 UTC
From: reichert@rtsg.mot.com
Message-ID: <3mjeqs$ik6@newdelph.cig.mot.com>
Source record: 113503

I've just worked up a circuit which I've installed on a
recently acquired FT-726R to provide Hang AGC. For those
not familiar with Hang AGC a little explanation.

When using the Slow (long RC) AGC the receiver takes forever
to
recover on strong signals. The Hang circuit still allows
for the long time constant but will always provide a rapid
discharge a fixed delay after the signal disappears, thus
the
apparent "hang" time.

If anyone is interested I'll supply the circuit if you send
me an SASE. Sorry no PC layout, I'll leave that to you.

Also made some 6, 2 Meter Module front end changes using
the
3SK205 Dual Gate GaAsFET. Will let you know how well it
works out when I get the beams up. So far they are
performing
great just listening off the 6 Meter dipole.

Currently working on an RF Delay circuit for the TX module
for
use with Ampliers/Preamps such that the preamps won't get
blown.
Will let the group know how that works out after it's
installed.
(Thanks to Pete, K9PW for the clue on this 726 bug.)

From: n7ws@aol.com
Message-ID: <3mi8sq$t0e@newsbf02.news.aol.com>
Source record: 113506

In article <dgfD69IwC.4qz@netcom.com> Dave WB0GAZ writes:

>>I play with direct conversion transceivers such as the old Ten-Tec
Power Mite series. In my location (Denver), I get interference from
a shortwave radio station (WWCR in Nashville, TN.) that runs on 13.845
MHz and is very strong much of the time (causing AM detection in the
receivers). I suspect they are in the megawatt range.

>>To add insult to injury, WWCR is christian broadcasting (I think
the callsign is meant to say "Christian Radio" for CR).

>>Anyway, it occured to me that I might be able to build a sharp
notch filter out of a single series resonant 13.845 MHz crystal.
I don't need tunability - just 20-30dB deep notch within 10 kHz of
13.845.

>>I have no other sources of interference like this, so if I notch
out 13.845, I'll be happy. I'll just consider it my contribution
to the church.

>>If I transform the 50 ohm receiver path up to 500 ohms or so, wire
the crystal to shunt to ground, then transform back down to 50 ohms
(using broadband toroid transformers), will I achieve my desired
effect?
This might be an approach, Dave. However,one problem will be the fact that
the parallel resonant frequency of the crystal will be quite close by on
the high frequency side. It these guys are DSB AM, you might find that you
will notch the carrier and still have the upper sideband. So... you
probably won't meet your 10KHz BW rqmt.

I thought direct conversion was the PURPOSE of religious broadcasting, and
your trying to fight it :)

Forgive if this is off-topic, and will never do it again if it is, but thought
you Hams may have the expertise I'm looking for for my problem..
Help! All drove up and no where to go!!...

Have a Conner CP-3100 SCSI-1, 3.5" 104 Mb drive with no setup sheet and no
idea
as to what jumpers do what, what jumpers or plugs are for the terminator
resistor pack (or if it even needs one, a jumper may activate a built-in
terminator for all I know!). Have all the connectors and screws for
mounting it in my Amiga 2000 on the GVP A4008 SCSI/RAM board, but...

I NEED to find out what jumpers and plugs do what, especially the ones
setting the SCSI ID and if the drive needs a resistor pack (& what size,
75 ohm?) & where would it go? If someone has a drive made around the
same time and could let me know so I could give a FAX number to send the
copy of the setup sheet/manual to (or transcribe it to text & send it to
me here) or my address or if local, where to arrange to pick up the copy
of the sheet/manual or get the info. If Conner Peripherals could provide
me with this sheet, what's their address, phone, AND FAX number(s)?

Here's what I have observed off the drive itself:

On the ID plate on the drive : On lower left of Drive enclosure:

John,
I saw a posting on the QRP list a few days ago regarding using threaded PVC pipe(?) as a coil form. Apparently it is available in sized up to 8 inch diameter and with some various thread pitches. Anyway, you wing your coil in the threads and then take a glue gun and run four stripes of glue over the coil at 90 degree spacing, and when dry -- just unscrew the form from the coil.

I do agree about the tax-man and NAFTA.

73,
Bruce -- W6TOY/3

N7>>>I play with direct conversion transceivers such as the old Ten-Tec
N7>Power Mite series. In my location (Denver), I get interference from
N7>a shortwave radio station (WWCR in Nashville, TN.) that runs on 13.845
N7>MHz and is very strong much of the time (causing AM detection in the
N7>receivers). I suspect they are in the megawatt range.

N7>>>To add insult to injury, WWCR is christian broadcasting (I think
N7>the callsign is meant to say "Christian Radio" for CR).

N7>>>Anyway, it occured to me that I might be able to build a sharp
N7>notch filter out of a single series resonant 13.845 MHz crystal.
N7>I don't need tunability - just 20-30dB deep notch within 10 kHz of
N7>13.845.

N7>>>I have no other sources of interference like this, so if I notch
N7>out 13.845, I'll be happy. I'll just consider it my contribution
N7>to the church.

N7>>>If I transform the 50 ohm receiver path up to 500 ohms or so, wire
N7>the crystal to shunt to ground, then transform back down to 50 ohms
N7>(using broadband toroid transformers), will I achieve my desired
N7>effect?
N7>This might be an approach, Dave. However,one problem will be the fact that
N7>the parallel resonant frequency of the crystal will be quite close by on
N7>the high frequency side. It these guys are DSB AM, you might find that you
N7>will notch the carrier and still have the upper sideband. So... you
N7>probably won't meet your 10KHz BW rqmt.

N7>I thought direct conversion was the PURPOSE of religious broadcasting, and
N7>your trying to fight it :)

N7>73,
N7>Wes Stewart, N7WS
N7>n7ws@aol.com

Hehe, cute Wes.... as a former professional crystal grinder
(at Cathodeon CRystals, Linton in England 1970-71, irrelevant really
but included it as recreational info :-)
I can tell you that one should stagger the 13.845 crystals to achieve
broader null. This is quite easy. He can just make a filter network

wit several xtals from say 13.840 - 13.850 and that will null out the monster signal from WWCR. It still won't help if he is after some weak DX station within 5 - 10 kHz of WWCR though.
Just my .02 cents worth!

>bump at 144 MHz, or will the effect be negligible?
>
>Steve

It will introduce an impedance bump at that high a frequency, but whether it will be a problem depends mostly on how fussy your transmitter output circuit is regarding SWR. For instance I have a 50 mHz amplifier which uses a modular output block with built-in SWR protection. At first I tried several plain old relays for antenna switching, even going so far as to modify them to bring out leads as short as possible. No luck. The output block sensed the impedance bump and reduced power way down. I finally gave up and bought a REAL vhf coax relay ($$) and the problem was solved.

Your mileage will definitely vary.

: ZL2APE@ZL2WA.#NZL.OC

Jim,
You might want to look into a programme called ALMOND, an updated version of which is called SCALC, both of which are available as shareware. I wrote ALMOND back in 1981-1982. It performs circuit analysis and optimization in terms of S-parameters.
You might also consider the shareware version of PSPICE, which is also available on a number of bulletin boards.

SCALC is avaiable from Ian White, G3SEK, at:

g3sek@ifwtech.demon.co.uk

-I am intrigued by an ad by US Cyberlabs for a 3 axis CNC kit for
-prototyping PC boards or 3D machining using a PC and a Dremel tool.
-Has anyone seen or used one of these? Any info or opinions on the
-unit or US Cyberlabs will be appreciated.

Don't get it. Look over in comp.robotics for the problems that
people have had with it (apparantly it is a very poor mechanical
design with lots of slop and backlash). I have never seen any
US Cyberlabs/Nick Goss products, so I can't say for sure. All I know
is after *repeated* phone calls and letters, I could never get him
to send me a catalog, even after I promised some large orders on
behalf of my radio club. If he can't send out a catalog, I certainly
wont send him money. After speaking with the editors of Radio Electronics
(now Electronics Now) and Nuts and Volts, apparantly others were also
having problems contacting him to purchase the 'custom' parts he used
in his designs. I haven't seen one of his articles in a while. It's too
bad, since he had some interesting projects.

/mike

BTW, he still insists that there is a 'communicator' class of Ham license,
and you don't need a license to transmit on the ham bands with less than
100 mW...

1415. 222 MHz Amplifier

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-14 00:00:00 UTC
From: pbutlalj@ia.net
Message-ID: <3ml1m9$5jr@allanon.ia.net>
Source record: 113513

Hello All,

I am interested in building the 222 MHz ransverter that is in the latest ARRL handbook. The artwork for the boards has been obtained and printed out. The list of parts is not too difficult to find but the one problem that I can see with the unit is the transmit power level. The unit is designed with an output of +6dBm. Now this is fine for across the yard or the basement type of work but I would like something that can be useful for weak signal work and also to operate with the 56Kb packet modems sold by GRAPE.

What it seems is required is an amplifier of some type that would take the 4 mW from the transverter to about 25 watts into the antenna. Does anyone have any ideas as to the best way to accomplish this at 222 MHz? The output of the transverter is a 50 ohm impedance. Also the article in the handbool says that there will be additional filtering required to meet the FCC rules.

I look forward to hearing back from people on how to do this,
Thanks for your help.

Many of the modern general coverage HR recieviers are
up conversion RX's with their first IF at 45 or 75Mhz.

What kind of filter do they use for the first IF?

Crystal? Ceramic?

Can one easily design a crystal filter to operate
on the crystal overtone frequency???

There are many references to building crystal filters, but I have
seen littel reference to using the OverTone.

Thanks in advance for any responses.

Sorry, Jeff, there _are_ chip inductors, though they tend to have very small inductance _and_ current carrying ratings. There are lots of folks making surface-mount inductors (both chokes and transformers). Suggest you run over to the library and thumb through something like Electronic Products magazine once in a while to keep up to date on what's available in terms of parts! ;-)

As for the gent who's looking for the airdux and miniductor stuff, you might also check with Antique Electronic Supply here in Tempe. They've got a _huge_ warehouse of parts that most folks like Brian think are "obsolete"... I've seen parts in there that I've used as recently as 15 years ago, and they probably have some that are even newer than that.

73,
Clark

P.S. The chip inductors are made in a similar fashion to chip capacitors, except that instead of having alternating plates that are insulated, they have an area that runs "around the outside" of each "plate", with adjacent "plates" being connected, so that there's a "squared off" coil structure formed. Not used a lot, but they've been commercially available for at least 5 years.

Source record: 113422

As I've always been pretty good at construcing things with Gilbert Erector Sets (sez the young guys, "With a WHAT??"), I've always wanted to homebrew air variables, rotary inductors, etc. However, I have yet to find anything on the composition of ceramic insulators, or how I might fo about making them. I do know that the stuff that normally comes from crafts shops is not what I want, but that's the limit of my expertise on the subject.

If I could come up with a way, I'd actually consider buying a small kiln and maybe pay it off by making and selling the good old fashined ceramic dog-bone type antenna insulators. I haven't seen THEM in a while.

Delusions of becoming the Henry Ford of dog-bone insulators aside, are there any ceramics experts out there, or does anybody know of a reference where I can find out how to make ceramic insulators?

> before winding?? Worth a try.

Two solutions (no pun intended) come to mind. One is WD-40 sprayed on the form first and the other is to use the release coating used to glass bed rifle stocks. The latter would probably have a better chance of working.

If you were to wind the coil on threaded <steel> pipe, then you could heat it up to a temp that will melt a plastic rod, press it onto the coil and let it cool. We're talking about getting fancy now, but if you could make a steel form with cutouts at 0, 90, 180, and 270 degrees, you could push the plastic rods in from behind. I'll bet that's very similar to what B&W did.

Or, you could epoxy plastic (Lexan?) strips to the outside of the coil.

Zack are you trying to say that Ian is wrong in stating what IS!! necessary for screen regulation for 4cx series tetrodes.The imd does deteriorate rapidly if this sort of regulation is not adhered to.In the 80's John Nelson G4FRX now GW4FRX did exhaustive work on this very subject.My own personal experience of this is a local amateur who had a 'commercial' 4cx250b amp which had inadequate screen regulation,he wreaked havoc!He fitted a 'retro'kit which was available from Melvyn Noakes G4JZQ(I think that was his call)and the band became habitable again.

Of course you can 'get away' with a string of zeners but to get the performance which is available from these tubes Ians recommendations are good ones.Ask EIMAC I'm sure they will agree.

Yes, but I don't think you'd be using chip inductors in a 100-watt or KW transmatch!

(I'll admit I roll my own.)

I did get some B&W Miniductor about 7 years ago from a local place that was going out of business...last I've seen of it except at hamfests.

Guess we just need to do what we're known best for as radio amateurs...be creative!

Paul,
It's very likely that they used a SAW (Surface Accoustic Wave)
filter for the first IF. These have been in common usage for the last
10-20 years or so, and are quite inexpensive now. Sawtek is the largest
domestic manufacturer, and they have a very wide variety, particularly in
the region of 70 MHz.

>Bruce -- W6TOY/3
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>
Does any enterprising fellow out there have a machine to thread plastic pipe? I would be interested in buying 10 or 12 inch long sections of different diameters - say, 1 inch, 1.5 inch, 2 inch, 3 inch, etc. The standard pipe thread pitch would be fine.

I do see one possible problem with the glue gun - sticking to the form as well as the wire. Possibly the form could be coated with mold release before winding?? Worth a try.

1431. HF Amplifier using 811's

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-16 00:00:00 UTC
From: rvmathis@rvm.iii.net
Message-ID: <3mq2e1$1pk@news.iii.net>
Source record: 113432

I have been pricing tubes to replace the ones in my Dentron Amp and fell that maybe I should consider building an amp that uses more readily available tubes. All of the tube dealers recommend the 811's as being a tube that will be around for a long time. Any comments on this choice in tube, good plans, and anything else that applies is more than welcome. I have one article from QST on a four tube KW amp that looks interesting.

Thanks in advance

1432. Homebrewing your own transistors

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-16 00:00:00 UTC
From: billhar@spaceworks.com
Message-ID: <D741H1.3sE@spaceworks.com>
Source record: 113433

Subject: Build a Transistor, or how to homebrew at only twice the cost
of factory built.

"Rig here is homebrew, all solid state. I even hand made the
the transistors."

Taking a few ready made parts and assembling them into a working
unit is pretty easy. If you really want to refine the art of
homebrewing, try building your own transistors.
The May 1949 issue of Radio-Electronics features an article on how to
construct a transistor using the parts of two 1N34 crystal diodes. The
sensational announcement of the crystal triode or transistor had been made
only a few months before and experimenters had been waiting patently for
the manufactured version of the device. In the meantime a few impatient
experimenters were rolling their own.

CONSTRUCTION

The 1N34 consists of two threaded brass end plugs which are screwed
into opposite ends of a small ceramic tube with a tungsten wire
whisker soldered to one of the plugs and the other end rests upon the
germanium wafer. The wafer is soldered to the end of a brass pin which
passes through a hole in the other end plug and held by a set screw.
The article describes how to dissemble the two diodes, and using the
brass plugs and ceramic tube from one, with a jeweler's saw, cut one
of the brass plugs in half. Next, using the tungsten wires taken from
the diodes, solder one to each half of the brass plug. Using Duco
cement, fasten the two halves together with an insulating separator
made of Lexan or Plexiglas 1/64 inch thick. Next, using a pair of
tweezers, bend the tips of the whiskers together until they have the
smallest separation without touching. Screw the two-whiskered plug
back into the ceramic tube and the other germanium-holding plug into
the other end. There is a hole in the side of the ceramic tube which
was used for electrical adjustment when the 1N34 was manufactured. It
was then filled with wax. Having removed the wax during disassembly of
the diode, view the whiskers though the hole using a magnifying glass
and make sure the whiskers are not twisted or touching each other. If
so, use a needle to separate them, if they are too far apart, push them
together and make sure they are in contact with the germanium disc.
The final step is to solder a wire pig-tale lead to each half of the
split whisker plug and also to the plug on the opposite end which holds
the germanium disc.

ADJUSTMENT

The article goes on to describe how to hook up batteries and two milliamp meters in the emitter and collector circuits to determine the operating characteristics of the device. The author reports that he has constructed devices with transconductances of 1,000 to 5,000 which is comparable to such tubes as 6K5, 6SQ7, 6T7, ect.
After all adjustments are completed, the side hole in the ceramic tube should be closed with a bit of Scotch tape.

Article by Rufus P. Turner, K6AI

So there you have it. If you really want to get into homebrew, try constructing your own transistors. Next month we will learn how to construct a 4-1000 amplifier tube using a mayonnaise jar, parts from an old VCR and a 1963 Volkswagen.

I vaguely recall some circuits in some EE texts that use op amps,
resistors, and capacitors to realize a pure inductance. Doing away
with the actual coil would make it easy to create chip inductors.
Not sure about the range on feasible inductances or current limits
on stuff like this, though.

1434. Need info on Sat rotor controllers

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-16 00:00:00 UTC
From: n9rze@firefly.prairienet.org
Message-ID: <n9rze-1604950252460001@ruger-4.slip.uiuc.edu>
Source record: 113435

I've been looking into building my own dish for S-band operation. The current rotors could not hold up a 6' dish. So I need to build a custom platform. In doing so I use a standard heavy duty rotor for the azimuth, but for the elevation I would use a screw-jack. Thing is, the screw-jack uses a reed switch to tell the controller how many rotations it has moved. But, as far as I can tell, amateur equipment uses pots to tell the controllers where they are. This is no problem, I would put a pot onto the elevation assembly. But what I don't know is, what info do the controllers get. How do they know where the rotors are pointing? Such as the AEA ST1, does it have preset memories for the various commercial rotors? Can I tell it a custom setting for my setup? As in, it ask's for me to point to 0 degrees elevation then save that resistance value, then point to 90 degrees elevation and save that too. Then the controller knows from what values to work with. Thus I've solved my delema for a custom controller. I'm interestd in any and all controllers out there, not just the AEA ST1. Thanks in advance.

> I picked up an IP-17 at a hamfest here two months ago for a mere >$25. It worked, but I had to repaint the case shells. The original >paint had gone soft a pliable for some reason, and it couldn't be saved.
>

Hmmm. I picked up an IP-17 several years ago that also had soft (tacky) paint - very easy to scrap off with a fingernail. I ended up removing all the paint and leaving the case shells just bare metal.

However, this is not the first piece of gear that I've seen with soft pliable paint. I picked up a piece of homebrew gear that was inside a commercial box (ZERO box?), and the paint on this box had also become tacky. Again, removed all the paint.

I guess the paint originally used on these chassis has become unstable and gone soft over time. I hope they still aren't using it!

- Jeff

By the way, Heath still sells replacement transformers for the IP-17. I needed to replacement mine this last December and was very happy to find they still had them. Not cheap (about $55), but if you need it, you need it! Don't know how many they have left, though.

Where can I get copy of this work? While I agree that zeners aren't usually enough, I disagree that it has to be millivolts to be effective. I asked a couple Engineers at Eimac and they are puzzeled about the millivolts too as long as there is some dynamic regulation from a cap.

What I found here was that if the screen was held within a percent or so, the IMD from typical radios (only -30 to -35 dB on the ones I tested) was much worse than the tube. I wonder why this difference? I also found a cathode resistor for negative feedback helped substantially.

> a lower IF I could buy some IC making the job. But I havent
> been able to find any IC doing the job at 201MHz.
>
> Maybee you know of some suitable device or solution?

If you use two IF's you can make the first one 201MHz to get a good image
rejection and the second one much lower where gain and narrow bandwidth are
easier to achive. If you are looking at wide signals then the first IF
should be around 40-60MHz, if narrow (3-10kHz) then a 10.7MHz if woukd seem
suitable. Crystal filters are obtainable for 10.7 & in the 40-70MHz range.

This message describes the rec.radio.amateur.*, rec.radio.cb,
rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet
mailing list counterparts and complements. It is intended to serve as a
guide for the new reader on what to find where. Questions and comments may
be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October
1994 to add the discussion of non-Usenet mailing lists and streamline most
of the history discussion, and to change the moderator information for
rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became
progressively higher. First one by one, and then as part of two
reorganizations, what was once one group became many. In the process,
developments elsewhere on the net were reflected in the groups as they were
created, most notably the change to place all of the ham radio groups in one
hierarchy.

The collection of newsgroups continues to grow as more people join the net,
and as more topics of discussion gain volume, I expect to see more groups be
created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the
notable exception being rec.radio.swap. There are also a few mailing lists
that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them,
and not to the groups that aren't. The whole idea of having different
```

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

I need a power supply transformer for a Hammurlund receiver, specifically the HQ-170. Anybody got one of those beasts?

Also -- need the crystal calibrator crystal

And.... a knob (just one) for the antenna tweaker.

Thanks for your help! Reply via e-mail. 73s Carl

Are these the inductors disguised as 1/8 Watt resistors? Someone gave
me a bunch of these and also some capacitors disguised as resistors,
too. The dang pastel color bands are so thin that I almost need
a magnifying glass to see 'em.

I know absolutely nothing about oscilloscopes but I have an old RCA oscillosope I found at an estate sale which I have no need for. Only asking what I paid for it -- $10 plus shipping +COD.

1449. DigiVFO article in QST

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-17 00:00:00 UTC
From: alb0@roger.gte.com
Message-ID: <3mu4cr$r32@ceylon.gte.com>
Source record: 113450

The DigiVFO article highlighted a rather interesting IC:
specifically, it was a numerically-operated oscillator.
I must be out of the loop (and not just the phase-locked
kind!) - I had never heard of this chip before! The
homebrew possibilities are fantastic, though. It seems
like this chip could be really useful for building
homebrew transceivers and sweep generators.

Has anyone done anything with this chip? It looks
like quite a gem.

They are not the easiest parts in the world to locate. I obtained the MPN3700 diodes back in November from Hamilton/Hallmark. Newark Electronics also carries them, but they were on backorder at the time. If I remember correctly, they were $.76/ea. from Hamilton/Hallmark and $.95/ea. from Newark, but both establishments are large supply houses and have $25 minimum order requirements. If you can't find a phone number for your nearest sales branch, Hamilton/Hallmark can be reached in Peabody MA at 508-531-7430 and Newark Electronics can be reached in Marlboro MA at 508-229-2200. (Newark also lists a phone number to obtain catalogs of 1-800-298-3133 ext. 48 if you want to try that.) The MPN3700 is available in both a standard and surface mount package.

I installed the diodes in the front end filter and preamp/attenuator stages of my Icom R71A receiver, and they seem to work fine.

1451. Any Designs/ parts for Spread spectrum?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-17 00:00:00 UTC
From: henniger@cisco.com
Message-ID: <henniger.798155589@cisco.com>
Source record: 113452

Hello all.

I am interested in putting together a simple spread spectrum
system.

Is there any place that sells parts that would work?

Frequency hopping is okay.

Computer external control might be nice to allow easy prototyping
of different PN sequences/ resync-ing / etc.

I took apart a Uniden 9100 900Mhz SS phone and found a nice small
little RF transciever subassembly.. be cool to have a few of those.

If you know of any parts/pieces (or ancilliary facts like computer control)

I'm very interested,

Mick

1453. CHIP Inductors

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-17 00:00:00 UTC
From: CNS@psimemphis.COM
Message-ID: <199504171228.MAA06662@chaos.magibox.net>
Source record: 113454

I've seen several comments about "never heard of CHIP inductors".

Both Newark and Digikey carry Surface Mount (ie. CHIP, SMT, SMD)
inductors, in both fixed values (10nH - 2200uH) and adjustable
(0.10uH - 4.0mH). They have form factors like 2.5mm x 3.2mm for fix
inductors and 5.0mm x 5.2mm for variable. Newark carries muRata and
Digikey carries TOKO.

Of course, their current ratings are measured in mA.

For a Newark catalog call 1-800-298-3133 ext 48.
For a Digikey catalog call 1-800-344-4539.

isn't the problem something along the lines of the phone line modems don't
like working half duplex? something about training and all that that goes on
nicely on a phone line isn't there on a radio link. might be a signal plus noise
to noise ratio problem as well....

Haven't heard of it before, Drew. I would like to get a spec sheet on it
to find out how it is controlled. Us Mac users won't be able to use the
author's PC program. Also, it if it has a 90 degree (quadrature) output,
it could be handy to use with Rick Campbell's single-signal DC receivrs
and transmitters which he dexcribed in QST a couple of years ago.

Wlll, I'm sure this won't help you with your request but the Alinco DJ-F1T
has the well hidden feature that you can set it to transmit a DTMF "C" when
the PTT is released. I have never used it but I did have to figure out how
to turn it off when a friend got button happy and turned it on for me. I'm
not sure why they built this in but I guess it makes as much sense as having
Kenwood put a video game on the radio :-)

1458. Question about modifying non-crystal VHF oscillator

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-17 00:00:00 UTC
From: peterson@physc1.byu.edu
Message-ID: <1995Apr17.101632.2184@physc1.byu.edu>
Source record: 113459

I am fiddling with a VHF oscillator that I would like to change the frequency on but rather than blindly changing components I would like to attack this with a little background. I looked in a book of oscillator circuits and found that it most resembles the Butler Common Base with inductive tap. However, the only information I have on that circuit uses a crystal to set the frequency and the one in question has no crystal. If anyone is acquainted with the characteristics and design of this type of oscillator without the crystal or knows of a good reference book that covers this I would greatly appreciate it.

Thanks in advance and 73,

Bryan Peterson, KI7TD

Yes, I thought of that immediately when I was reading the article.
The control of the chip is no problem for me (I have a PC), but Mac
people will have to work something out. What also crossed my mind
was devising some way of getting maybe a dozen constant-memory
values that could be stored when the computer is off. That way,
the user could get a dozen frequencies for portable work. Sort
of like a rock-bound rig, but with more rocks!

QST, April 1992, p. 76 Technical Correspondence (with corrections in Feedback,Jul 1992, page 73), the formulas behind this RF Design article/software. With a little careful work, you can plug it into a spreadsheet or BASIc program (I have mine in Excel). The work was done in 1910 or so! (The research, not my Excel sheet :-))

>Anybody see other formulas for inductance?

There was an article in QST (April 1992) researching a more accurate formula.
I wrote the following program based on it.

```
/*
* solenoid - program to calculate the inductance of a solenoidal coil of wire
*
* based on the Technical Correspondance article
* "Accurate Single-Layer-Solenoid Inductance Calculations" by Hank Meyer,
* W6GGV, from QST magazine April 1992 (pp 76-77) plus corrections not yet
* published as of May.
*
* usage:
* with no arguments, prompts for number of turns, coil length,
* coil inner diameter ("mandrel diameter"), and wire size or gauge.
* Enter wire gauge as #16 (or =16) for 16 AWG; enter wire size in
* inches as a number, or mils by suffixing number with m.
* with 4 arguments: number of turns, coil length, ID, wire size
* all specified as above.
* with something other than 0 or 4 arguments, displays a terse usage
* message.
*
* This program written by John Woods, jfw@funhouse.com, 19 May 1992.
* All Rights Reversed (K).
*
* Requires strtol() and strtod() which are common pre-ANSI library
* extensions, as well as being official ANSI functions. This isn't
* necessarily the best code in the world, but it works.
*/
#include <stdio.h>
#include <math.h>

1466. Re: internal modem>TNCvia phone cable

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-18 00:00:00 UTC
From: n6315@pnet16.navy.mil
Message-ID: <D791E1.Fn7@nctams1.uucp>
Source record: 113375
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.digital.misc

I can see where you could easily use phone modems to access a TNC in a
remote location. As far as over the air could be a problem, the first
one I can think of would be fairly easy to remedy, the second maybe not.

1. Your high speed modems use PSK (I believe it's QPSK, but I'm not sure.),
this can be overcome by connecting to the radio just like a 9600 BPS TNC.

2. Phone modems use one pair of leads for TX and RX audio. I'm not sure
which brands still allow you to set the modem for leased-line operation.
This would arrange two pairs in the RJ-11 connector, one for each.

It should be fairly easy to tap into the RS-232/EIA-232 for the CTS line,
and make use of that for your keyline. I'm not sure how effective this
would be, due to the modem being made for full duplex. Even 'half duplex'
isn't truly simplex, so you will probably run into problems there too.

INET: n6315@pnet16.navy.mil
The voltage mentioned by Dave might possibly hurt your relays. Most
of the teletypes in Naval use have been running on Low-Level (+/- 6V).
You could try that first, it won't hurt.

>Jack WB3U

It's for the AIWA MX-1 PAL/NTSC VCR (with digital converter). If has a
standard NTSC demod and RF mod. I need it to tune PAL RF signals, so I need
to replace 2 ceramic filters for the audio demod, and a ceramic trap for the
audio carrier in the video signal. The SAW for the IF should work fine for
PAL signals, even if it's a bit narrow.
The RF mod only needs a retune of the audio carrier, using the adjustable
inductor.
Since the tuner has AFC, it locks to channels several MHz off center.

Scrounging parts for WARC bands on my recently (yes, recently) built HW9.
What is a BA-244 diode? Is there an equivilant? Tried substituting a
IN914 which does not work! Before I order 16 of them from Heathkit at 43
cents each (plus shipping) I thought I might ask if there is a substitute
that would work.
Thanks!

1473. Re: Transmitter tube info wanted.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-18 00:00:00 UTC
From: magnee@telepost.no
Message-ID: <3n14i8$kvf@nms.telepost.no>
Source record: 113382

In article <3mveko$s3s@nuclear.microserve.net>, jackl@pinetree.microserve.com (WB3U) says:

Thank you for your quick response Jack.

>I looked for this in a 1947 edition of "The Radio Handbook", which lists a large
>number of older receiving and transmitting tubes. No luck.
>
>Your tube is either *very* old, very rare, or bears a number unrelated to its
>actual type number.

I do not think it is _that_ old. I'd rather guess '60 - '70,
but I may be wrong. It may be rare, I guess.

It's a glass tube, about 22 cm high, and a diameter of about
11 cm. The base on the tube is about 5 cm high (included in the
22 cm), with a diameter on about 8 cm. It has the anode and
cathode connections on the top, and the socket is marked f and f,
g1, g2 and g3 with pencil. Inside the glass, on a base plate there
is e little metal strip with the markings "G 340 / 117" as a serial
number? The pins at the base is 8 mm thick and 25 mm long, and
those of the anode and cathode at the top are 14 mm thick
and 30 mm long. As you can see it is a large tube, designed
for carrying high current.

>Sorry I couldn't be more help. BTW, what's it used in?

The tube was found in my father radio shack after he passed away.
There was many tubes there, but this tube is among the few I did'n
sell. My father was a ham (LA3SA) and was working at a radio station.
The tube may have come from that radio station. I do not know what
use it had, or in what equipment it was used. I am only guessing
when I say that it is a transmitter tube. But it is unlikey that
my father had any tube of this construction, _not_ related to
transmitters. This tube looks like a tube BROWN BOVERI would
have designed, when they made a transmitter, and not intend for
general use.

I hope this helps.

Several years ago, I purchased and built a Doppler DF kit from Dick
Smith Electronics. It sounds just like what you're describing. I'm
not sure if the company is still in business (I seem to remember them
being in Australia). The kit seemed well-designed--not quite
Heathkit quality, but pretty good nonetheless. I used it for a
while and then sold it.

1475. Need Help finding Fused Line Plug

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-18 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <3mvdv2$s3s@nuclear.microserve.net>
Source record: 113461

I am in the process of restoring an older HF amplifier that originally used a fused (2-3AG) line plug. The plug was missing when I purchased the unit, and in its place the owner had installed a double-fused, plug-in adaptor.

The adaptor has now failed from age and I need either an original type plug that I can attach to the line cord, or another 120 VAC fused adaptor.

Anyone out there know if these items are still made, or whether any suppliers have NOS?

Thanks and 73,

Jack WB3U

PS: Also need some silver-plated copper strap for the tank, about 3/8 to 1/2" wide. If anyone has this, I'd very much like to purchase a foot or so.

1477. Re: HF Amplifier using 811's

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-18 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <3mvgg0$s3s@nuclear.microserve.net>
Source record: 113463

Hi Ron:

I picked up an old Gonset with (4) 811A's about three years ago and am just now starting to restore it. My purchase decision was made on the basis of the finals, at a time when 811A's were not plentiful. The (RCA) tubes which are in the amplifier now are the result of a lucky find at a local hamfest shortly after my purchase. Since that time, I have been pleased to see that 811A's seem to be making a comeback and I think they are even being manufactured in the U.S. again.

The appeal of these tubes is their price and efficiency. For $60 to $80, a set of four will run 1KW CW and 1500W SSB input with a good power supply. Output at 1KW input (in a well designed amplifier) approaches 750 watts in Class AB.

Although 3-500Z's provide greater plate dissipation, they will not provide this output level when running CW at the legal limit. Note that "legal limit" is the key here - a pair of 3-500Z's can, of course, run 2KW input on CW no sweat.

Regarding homebrew, the 811A's will undoubtedly provide a less expensive project, unless you have a very well stocked junkbox. Everything is smaller - filter caps, plate tune cap, plate choke, power transformer etc. Also, the sockets are much less expensive and chimneys are unnecessary.

As a final note, I strongly recommend that you build input filters for the amp, rather than simply feeding drive directly to the cathodes. Even if this means adding another bandswitch, it's worth it. I have a schematic with component values if you need it.

73,

Jack WB3U

Is this a PAL tuner? If so, JVC, Sony etc. should be able to direct you to a source of parts for their overseas models. Failing this, SAW filters for PAL are available through U.S. distributors, although they get kinda pricey for homebrew projects. You might get a lead on these from some of the LPTV manufacturers who often have to replace SAW's in their modulators in preparation for export.

Neil, hard drive problems can often be resolved through the following news group:

comp.sys.ibm.pc.hardware.storage

Conner's tech support number is 1-800-4CONNER. They can probably give you
the info you need on the phone, and they also have a "fax-back" service if you have
a fax number. When you call, the automated system takes a good while to get
through, but don't hang up. They *will* answer.

Hope this helps.

Well, folks, I was happy to see such a nice, simple DDS in that there DigiVFO. However, just be aware of its limitations. The author implied that his TR7 had a PLL that would take care of a lot of the spurs. But those of us who put the output directly into our various homebrew receivers are likely to be a tad disappointed in the received signal spurs (look at 'em! only 70 dB down, with some 60 dB) and noise level, except for casual use. A band full of contesters would show this thing's weaknesses immediately.

As a transmitter VFO, this would meet specs pretty well directly.

Guess we'd have to apply some of Rohde's PLL tricks in the issue a few months before to really clean this baby up.

1484. balan to ATU - is it still UNBAL 52 ohms?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-19 00:00:00 UTC
From: spike@biosci.uq.oz.au
Message-ID: <3n2006$oho@dingo.cc.uq.oz.au>
Source record: 113385

Even though this is a transmit amateur group,
I thought I'd ask this receive only (SWL) question:

Does the ATU side of the balan (toloroid
transformer) stay UNBAL at 52 ohms?

In Chap.34 ARRL handbook (1992?) I read a
ATU design which suggests an optional balun add-on. I wish
make a ATU with two switchable balans (1:1 & 1:9).
The balanced input (Z 100-500+ ohms) connects to a toloroid
transformer which is wired into a ATU L-network which
then outputs to a 52 ohm coax to my receiver.

So, does the balan reduce some impedence, then the ATU
reduce the rest? OR does the ATU "see" unbalanced 52 ohms from
the balan?

Does the ATU wiring mess-up the 52 ohm unbalanced fields?

I would like to place the ATU with balan at the feed point
of my 1/2 wavelength loop and run 52 ohm coax to the receiver.
Alternative: balan at feed point of loop and run coax to
the ATU near receiver.

1485. Re: DigiVFO article in QST

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-19 00:00:00 UTC
From: tvr@cnmat.CNMAT.Berkeley.EDU
Message-ID: <TVR.95Apr19004708@cnmat.CNMAT.Berkeley.EDU>
Source record: 113386

The DigiVFO article highlighted a rather interesting IC:
specifically, it was a numerically-operated oscillator.
I must be out of the loop (and not just the phase-locked
kind!) - I had never heard of this chip before! The
homebrew possibilities are fantastic, though. It seems
like this chip could be really useful for building
homebrew transceivers and sweep generators.

Has anyone done anything with this chip? It looks
like quite a gem.

I'm not sure what article you're referring to here. In the "JulieBoard"
article (_73 Amateur Radio Today_, August 1993, pp. 40-46), they use a
Harris HSP45102, one of a family of "numerically controlled oscillators",
which is also used in the recent _QST_ article ("A High-Performance Hybrid
Frequency Synthesizer", March 1995, pp. 30-38 [which is a report, not a
project]).

The family includes the HSP45102, HSP45106, and HSP45116; but only the first
is accessible to those of us who aren't ready for post-DIP mounting technology
(e.g. beyond vanilla PC cards). These are not yet available in PostScript
format last i checked, but they are available in fax form via their WWW
server (or more conventional means):

http://rel.semi.harris.com:80/docs/AnswerFAX/Digital_Signal_Processing.html

Which covers the first half of the following:

Haven't heard of it before, Drew. I would like to get a spec sheet on it
to find out how it is controlled. Us Mac users won't be able to use the
author's PC program. Also, it if it has a 90 degree (quadrature) output,
it could be handy to use with Rick Campbell's single-signal DC receivrs
and transmitters which he described in QST a couple of years ago.
[_QST_: January 1993, pp. 32-40 (correction April, p. 75);
April, pp. 27-31; VHF & above, May, pp. 29-34]

The HSP45106 and i believe also the HSP45116 do have quadrature output, but
are considerably more complex and require more thought to program. You'll
need to deal with 'pin cushion' style ICs (PLCC) and that almost certainly
means CAD generated PC boards. Maybe someone else can tell us whether that
can be done plausibly with xerographic toner-transfer resist techniques.
Their DAC/ADC data sheetsd chips are available in PostScript form, so please
save everyone trouble by getting those if you can use that format.

You may also want to think about more conventional PPL techniques as well,
especially above the HF bands. Some of these are discussed in recent ARRL
handbooks (for 1993, pp. 10-14 to 10-17 cover VHF/UHF applications), and

you may be able to get useful information out of Motorola as well. You may want to look at one of their synthesized 46/49 MHz portable telephone applications to get an idea how a minimal application might work (MC13135 FM receiever datasheet, p. 7). [Of course, you'll need a synthesizer chip that has more than a 20 word ROM to control it.] Their fax service is available at:

http://motserv.indirect.com/home2/fax_rqst.html

You generally have to know more about what you're looking for, although their "Master Selection Guide" is searchable and pages available in .GIF format. Some of their datasheets contain artwork for sample applications, which can help you get started (especially for surface-mount-only devices), and others mention amateur radio applications.

There are certainly more DDS and synthesizer chips out there, as well as other devices which generate quadrature output (such as [i think] Qualcomm and MiniCircuits); i've merely listed these as being WWW accessible. Of course, you should take this all with a grain of salt, as i, too, am just learning at this point.

I am looking for a cross referance to the following transistors:

ON614
ON642
BCX58
BCY58X
BDX539

I believe that these are European transistors and I would like to replace
these with more commonly known transistors

Thanks.

Well, Pagers ship bazillions of chip coils a year, since those tiny things are too small for a good 10 gauge airwound coil. In addition, Coilcraft is selling real wire wound chip inductors, down into the 50 mil by 80 mil footprint. Nice fine wire they use, also.

Yep, the circuit is called a gyrator. Very large inductances can
be synthesized using this circuit. The ft of the active device,
and it's gain, usually limits this method to the lower frequencies,
but that's exactly where you need large inductances. At higher
frequencies, the physical chip inductors can suffice, and of course
at VHF+ frequencies, strip line circuits are practical.

1490. Who Built This Receiver?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-19 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <3n3hvv$i38@nuclear.microserve.net>
Source record: 113391

I know this is a long shot, but it's worth a try.

About seven years ago, I gave away two KVG 9 MHz crystal filters to a guy who was building a receiver. The filters were new and I had mounted them on a homebrew PC board with switching diodes, mini RF chokes and decoupling caps.

I shipped the filters to this gentleman (I think he had a 5 call) and have wondered ever since how the project turned out. Unfortunately, I cannot identify the name or call from my logbook. The only other thing I remember is that I think he said he was in college at the time.

If the above describes you, or you know someone who built a receiver using these filters, drop me a line. BTW, my call at the time was WB5GGY.

Thanks and 73,

Jack WB3U

The problem is that you now need an op-amp that can sink a few hundred amps, no doubt.

But gyrator circuits can be used at higher frequencies. About ten years ago, I was using some of the National Semi video amplifiers as gyrators in the IF strip of a homebrew receiver. They had a high enough Ft, but they were really too noisy for the application so I had to shove a lot of broadband gain into the front end. No doubt the state of the art in op-amps has improved considerably.

I was, however, very disappointed that I couldn't get the same level of performance that I get from my Collins R-390A..... and it cost me a lot more to build the thing than the Collins cost me at the hamfest.

> works great from others...

The ARRL FM and Repeater Handbook has plans for a 2 meter duplexer.
The homebrew designs I have seen in use may work fine at times,
terrible at others. Duplexers seem extremely expensive but when you
get into making one for yourself you will surely, like me, think
several hundred dollars isn't so bad after all. The biggest problem
one faces withhomebrew duplexers is that even after all the headaches
of contructing and tuning it, mechanical stability is a problem,
especially with copper-clad PC board versions and even with the brass
or copper tubing versions... temperature swings will invariably detune
them. Then, if you put up with it long enough, the internal surface of
the duplexer will oxidize and develop intermittent problems where the
finger stock rubs the side of the cavity.
I've never built a complete duplexer; only filter cavities, and they
are pain enough.

1493. FT-726R Hang AGC Mod

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-19 00:00:00 UTC
From: Charles Reichert <reichert@cig.mot.com>
Message-ID: <3n3u3f$9ko@newdelph.cig.mot.com>
Source record: 113394

FYI

I've just worked up a circuit which I've installed on a
recently acquired FT-726R to provide Hang AGC. For those
not familiar with Hang AGC a little explanation.

When using the Slow (long RC) AGC the receiver takes forever to
recover on strong signals. The Hang circuit still allows
for the long time constant but will always provide a rapid
discharge a fixed delay after the signal disappears, thus the
apparent "hang" time.

If anyone is interested I'll supply the circuit if you send
me an SASE. Sorry no PC layout, I'll leave that to you.

1494. Mod for Icom737 not same for 737A-expanded RF

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-19 00:00:00 UTC
From: haworth@Direct.CA
Message-ID: <3n4745$oql@stud.Direct.CA>
Source record: 113395

Anyone else ever tried to mod. a 737A for expanded Rf work?? I understand the older 737 may be modified by cutting diode D3 (of the three diodes on the board D3-D4-D5).

However the 737A only has one diode labelled D303 and when cut the set is no longer operational.

Any help insorting this problem out would now be very deeply appreciated.

Please email me at <haworth@DIRECT.CA>

Many thanks

Steve, I'm not certain how Aiwa places that SAW in the IF, but if it's used to pass the entire video IF, you could have a problem. The chroma subcarrier in PAL systems is located approximately 4.5 MHz above the visual carrier, not 3.58 as in NTSC. An NTSC visual SAW is probably set for a bandwidth of 4.1 or 4.2 MHz. In other words, visual resolution may not suffer to a great extent, but the color subcarrier may be attenuated to unacceptable levels. This would result in B/W pics.

Steve -

Blue Skies is available for Macintosh from "ftp.tidbits.com". I'm not sure if it is available for PC's from that site. But if you did a Veronica serch for "Blue Skies" you could probably come up witha number of sites from which to download it.

The Univerity of Illinois (uiuc -- University of Illinois Urbana Champaign) ftp server has lots of weather maps and sattelite images as well. They also have a web site at http://www.atmos.uiuc.edu/wxworld/html/general . I'm sure there are more sites with weather pix. Once you get to one, you can usually use their pointers to access others. Let me know how it works out.

1498. Mosley says you can't wind coils????

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-20 00:00:00 UTC
From: "Jake A. Hellbach" <Jake_A._Hellbach@ccmail.mobil.com>
Message-ID: <3n6h6g$spg@dlsn31.dal.mobil.com>
Source record: 113318

My brother recently bought a used Mosley triband beam and when
he got it home he found one of the traps had been hit by lighting.
Trying to find a source of aluminum wire he called Mosley to see
if they would sell some to him. When the operator answered he
explained the story and there was a moment of silence on the
other end, then she said "Sir we don't recommend you wind our on
coils because it could blow up." Well when my brother regained his
composure he asked to speak to a tech who also told him you can't
wind your own coils because they (Mosley) have a special machine that
winds the coils and tests them.(But they would sell him a new coil).

I guess if Mosley says you can't wind coils then I should throw out
all my reference manuals!
Oh, my brother got the wire and he and the antenna are doing great.

So I'm writing this to all the homebrewers out there, BEWARE!!!!!
DON'T TRUST THAT COIL!!!!!!!!! (HI HI)

Jake KK5HY

P.S. We just had a "build the smallest cw transmitter contest" at my
local club. I built mine in a computer mouse case and used the left
button as the key. worked great!

The views here are my own and not of Mobil Oil Corporation.

1500. RFD: rec.radio.amateur.low-profile

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-20 00:00:00 UTC
From: adam@libertynet.org
Message-ID: <3n6bvc$mc9@rodan.UU.NET>
Source record: 113399
Cross-posted to: news.announce.newgroups,news.groups,rec.radio.amateur.antenna,rec.radio.amateur.misc,rec.radio.amateur.homebrew,rec.radio.amateur.equipment,rec.radio.amateur.space,rec.radio.amateur.policy

REQUEST FOR DISCUSSION (RFD)
unmoderated group rec.radio.amateur.low-profile

Group Name: rec.radio.amateur.low-profile
Proponent: Adam O'Donnell <adam@libertynet.org>
Distribution: worldwide
Newsgroups file: Operation of low-profile amateur radio stations.

This is a formal Request For Discussion on the creation of an unmoderated Usenet newsgroup, rec.radio.amateur.low-profile.

This RFD has been posted in accordance with the Guidelines for Newsgroup Creation. Its language is based on previously submitted RFDs.

****

NOTE: This is not a Call for Votes (CFV). Do not try to vote now.

This message begins a discussion period considering the creation of a rec.radio.amateur.low-profile newsgroup. Discussion should take place in news.groups. All follow-up posts should be made to news.groups.

Any comments such as "I vote yes for rec.radio.amateur.low-profile" will be treated only as a positive reaction to the proposed charter and not as a yes vote on the creation of the group. The CFV will contain instructions on how to vote.

****

CHARTER:

Rec.Radio.Amateur.Low-Profile is a newsgroup devoted to those amateurs who, for various reasons, must configure their radio stations to operate from restrictive areas such as condos, apartments, townhouses, neighborhoods with outdoor antenna restrictions, ships/boats, mobile homes,
or wherever they fry their burgers and call home.

The objective of this newsgroup is to encourage us to investigate means of employing all of the modes available to us for as many different purposes as possible. For examples, how can we use: FM (frequency modulation), CW (morse code),
SSB (Single Side Band: Voice on the Short Wave bands) on: LongWave, ShortWave, VHF (Very High Frequency), UHF (Ultra High Frequency), MicroWave, and Satellite.

Operators who use the newsgroup will be encouraged to describe in
detail their home station and how they solved the never-ending problem of
small city lots and housing development "no-antenna" contracts.

Rec.Radio.Amateur.Low-Profile will be an unmoderated newsgroup.
Users of the group are already experienced netiquette because of their
experience in Amateur Radio, which is a sort of Ladies/Gentleman's club.

A Rec.Radio.Amateur.Low-Profile FAQ will be posted a few weeks after the
creation of the newsgroup.

REASONING:

There are many newsgroups and mailing lists that exist on the
Internet for amateur radio antennas, low power operation, satellite
communications, etc. where operators in restrictive conditions post
continually post messages for help with their situation. In more cases
than not, the operator cannot find sufficient help on the 'group or list.

There should be a place where people who have solved their problems
with cramped quarters can post their problems to a group of knowledgable
amateurs.

I have conducted several informal polls and have discovered
that there are many amateurs (and, actually, non-amateurs) who would
very much favor and enjoy the creation of a newsgroup of this sort.

Distribution of RFD:

The complete official messages - RFD, CFV and vote results
will be posted to these required or affected newsgroups:
news.announce.newgroups, news.groups
rec.radio.amateur.antenna, rec.radio.amateur.misc,
rec.radio.amateur.homebrew, rec.radio.amateur.equiptment,
rec.radio.amateur.space, rec.radio.amateur.policy

Procedure for creating this newsgroup:

Interested parties are encouraged to comment on this proposal in
news.groups. Please post your comments *only* in news.groups.

After 21 days, if there appears to be a strong consensus in favor of
this proposal as it is written here, a CFV will be posted, which
will initiate the voting process; otherwise, discussion will
continue until a more refined proposal can be prepared.

After the CFV is posted, the voting period will be at least 21 days.
If the group passes by receiving 100 more YES votes than NO votes,
and (at least) two-thirds of the total vote is affirmative, the
newsgroup
rec.radio.amateur.low-profile will be created.

Again, please do *not* vote now. The voting process has not begun,
and your votes will be DISCARDED if you attempt to do so.

For more information on the newsgroup creation process, see the documents entitled "How to Create a New Usenet Newsgroup" and "Usenet Newsgroup Creation Companion", posted regularly to news.groups, news.announce.newusers, and news.answers, and available for ftp at rtfm.mit.edu in /pub/usenet/news.groups.

72, 73 (best regards)
Adam O'Donnell <adam@libertynet.org>

From: kbanke@qualcomm.com
Message-ID: <kbanke-200495072042@kbanke-mac.qualcomm.com>
Source record: 113401

I'm looking for surplus power GaAS FETs capable of >2 watts output at 2.4 GHz and above. This is for Amateur radio use & can be devices still in equipment or removed from equipment, mismarked, experimental, etc. Devices internally matched for higher frequncies are fine as I have found them usually to be easily rematched to lower frequencies. My interest is for devices probably up through Ku band which I can externally rematch for the 10 GHz amateur band. - Kerry N6IZW kbanke@qualcomm.com

MORE AND MORE USED MOTROLA HANDHELDS ARE SHOWING UP AT SALES, AND FESTS.
SOME ONE NEEDS TO LOOK INTO WRITING AN ARTICLE IN QST OR 73MAG ON THE BUILDING
OF PROGRAMMING CABLES AND SOME SORT OF COM PROG TO BE USED WITH THE VARIOUS
KINDS SUCH AS SABER , RADIUS, MTX-900. SO WE DON'T HAVE TO PAY TO HAVE THESE
UNITS RE-PROG'ED TO THE HAM FREQS..

1506. PEP measurement

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-20 00:00:00 UTC
From: jms@col.hp.com
Message-ID: <3n61jt$meh@nonews.col.hp.com>
Source record: 113405

In the May issue of QST, in the Lab Notes column is an article about measurement of Peak Envelope Power (PEP). The article states that PEP is measured by the following equation, with PEV=Peak Envelope Voltage: ((PEV * .707)^2)/50 for a 50 ohm system. I don't quite understand why a *peak* measurement is made by reducing the peak voltage to a .707 value. Even accepting that PEV * .707 is determining the *average* value instead of the RMS value (for RF) , as stated in the ARRL Amateur Radio Handbook, I still don't follow the reasoning. Using the above equation, it appears that a 1500W PEP output amplifier would have to be capable of outputting 3000W PEP on the *true* peaks in order to not "flat top" and produce excessive distortion products.

Additionally, the QST article stated that one can not measure CW or FM signals the same way, but it seems to me that what's valid for SSB is for CW/FM. Part 97 defines PEP as:

> (6) PEP (peak envelope power). The average power supplied to the >antenna transmission line by a transmitter during one RF cycle at the crest >of the modulation envelope taken under normal operating conditions.

O.K. Accepting that the 'average power during one RF cycle at the crest of the modulation envelope' is actually ((PEV * .707)^2)/50 and not ((PEV * .636)^2)/50 why would CW/FM be treated differently than SSB? And, am I correct about the true peak power being 2X the 'PEP' measured by the above methods?

Anyone care to clarify this for me?

BTW, I know that maybe this post should be in rec.radio.amateur.misc instead of here, but I *have* been working on my home brew linear and thought I could find an answer here. Thanks.

Mike, K0TER

1507. BAYCOM / RAMSEY / Packet info needed

Newsgroup: rec.radio.amateur.homebrew

Hi,
I've recently completed building the Norcal 40a and Explorer
20 meter kits, and had a ball doing so. I'm still very much in the
beginner/tyro stage--i.e, I can't just whip up a circuit myself or roll
my own gear "ugly" style.
I've always been taken with the romance and allure of tube gear,
and I wonder if there are any good kits out there for novices like me who
want to build hf tube gear simply for charm of it. Any ideas out there?
I ordered a catalog from Antique Electronic Supply today; I wonder
if there will be any ideas in there?

Matt

1510. RFD: rec.radio.amateur.low-profile

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-20 00:00:00 UTC
From: Adam O'Donnell <adam@libertynet.org>
Message-ID: <3n6qg4$mif@netnews.upenn.edu>
Source record: 113409

REQUEST FOR DISCUSSION (RFD)

Group Name: rec.radio.amateur.low-profile
Status: unmoderated
Proponent: Adam O'Donnell <adam@libertynet.org>
Distribution: world-wide
Newsgroups file: Discussion of the operation of a low-profile amateur radio
station.

This is a formal Request For Discussion on the creation of an unmoderated Usenet newsgroup, rec.radio.amateur.low-profile.

This RFD has been posted in accordance with the Guidelines for Newsgroup Creation. Its language is based on previously submitted RFDs.

****

NOTE: This is not a Call for Votes (CFV). Do not try to vote now.

This message begins a discussion period considering the creation of a rec.radio.amateur.low-profile newsgroup. Discussion should take place in news.groups. All follow-up posts should be made to news.groups.

Any comments such as "I vote yes for rec.radio.amateur.low-profile" will be treated only as a positive reaction to the proposed charter and not as a yes vote on the creation of the group. The CFV will contain instructions on how to vote.

****

CHARTER:

Rec.Radio.Amateur.Low-Profile is a newsgroup devoted to those amateurs who, for various reasons, must configure their radio stations to operate from restrictive areas such as condos, apartments, townhouses, neighborhoods with outdoor antenna restrictions, ships/boats, mobile homes,
or wherever they fry their burgers and call home.

The objective of this newsgroup is to encourage us to investigate means of employing all of the modes available to us for as many different purposes as possible. For examples, how can we use: FM (frequency modulation), CW (morse code),
SSB (Single Side Band: Voice on the Short Wave bands) on: LongWave, ShortWave, VHF (Very High Frequency), UHF (Ultra High Frequency), MicroWave, and Satellite.

Operators who use the newsgroup will be encouraged to describe in
detail their home station and how they solved the never-ending problem of
small city lots and housing development "no-antenna" contracts.

Rec.Radio.Amateur.Low-Profile will be an unmoderated newsgroup.
Users of the group are already experienced netiquette because of their
experience in Amateur Radio, which is a sort of Ladies/Gentleman's club.

A Rec.Radio.Amateur.Low-Profile FAQ will be posted a few weeks after the
creation of the newsgroup.

REASONING:

There are many newsgroups and mailing lists that exist on the
Internet for amateur radio antennas, low power operation, satellite
communications, etc. where operators in restrictive conditions post
continually post messages for help with their situation. In more cases
than not, the operator cannot find sufficient help on the 'group or list.

There should be a place where people who have solved their problems
with cramped quarters can post their problems to a group of knowledgable
amateurs.

I have conducted several informal polls and have discovered
that there are many amateurs (and, actually, non-amateurs) who would
very much favor and enjoy the creation of a newsgroup of this sort.

Distribution of RFD:

The complete official messages - RFD, CFV and vote results
will be posted to these required or affected newsgroups:
news.announce.newgroups, news.groups
rec.radio.amateur.antenna, rec.radio.amateur.misc,
rec.radio.amateur.homebrew, rec.radio.amateur.equiptment,
rec.radio.amateur.space, rec.radio.amateur.policy

Procedure for creating this newsgroup:

Interested parties are encouraged to comment on this proposal in
news.groups. Please post your comments *only* in news.groups.

After 21 days, if there appears to be a strong consensus in favor of
this proposal as it is written here, a CFV will be posted, which
will initiate the voting process; otherwise, discussion will
continue until a more refined proposal can be prepared.

After the CFV is posted, the voting period will be at least 21 days.
If the group passes by receiving 100 more YES votes than NO votes,
and (at least) two-thirds of the total vote is affirmative, the
newsgroup
rec.radio.amateur.low-profile will be created.

Again, please do *not* vote now. The voting process has not begun,
and your votes will be DISCARDED if you attempt to do so.

For more information on the newsgroup creation process, see the
documents entitled "How to Create a New Usenet Newsgroup" and
"Usenet Newsgroup Creation Companion", posted regularly to news.groups,
news.announce.newusers, and news.answers, and available for ftp at
rtfm.mit.edu in /pub/usenet/news.groups.

72, 73 (best regards)
Adam O'Donnell <adam@libertynet.org>

That's right. But the FCC talks about about peak *envelope* power, not
peak power.

>Additionally, the QST article stated that one can not measure CW or
>FM signals the same way, but it seems to me that what's valid for SSB

Sure you can. But the power limit for those modes is 750 watts, not
1500 watts.

>is for CW/FM. Part 97 defines PEP as:
>
>> (6) PEP (peak envelope power). The average power supplied to the

It isn't. FM has constant envelope, hence peak envelope power is the
same as average power. Same for CW (during key down).

>And, am I correct about the true peak power being 2X the 'PEP' measured
>by the above methods?

Yes, but that isn't what the FCC cares about.

>Steve, I'm not certain how Aiwa places that SAW in the IF, but if it's used to pass>the entire video IF, you could have a problem. The chroma subcarrier in PAL>systems is located approximately 4.5 MHz above the visual carrier, not 3.58 as>in NTSC. An NTSC visual SAW is probably set for a bandwidth of 4.1 or 4.2 MHz.>In other words, visual resolution may not suffer to a great extent, but the color>subcarrier may be attenuated to unacceptable levels. This would result in B/W pics.

>73,

>Jack WB3U

Well, the SAW filter is not very steep (Nyquist), and feeding the VCR a booming RF signal, there should be no problem. There is also a color AGC in the demod chip. If there is a problem, it could be with the audio at 5.5. The SAW is usually always before the audio "mixer". As for reducet video bandwidth, recording in the VHS system, half the signal is gone anyway. I'll give it a test as soon as I get the new ceramic filters.

Stainless steel is the best material to make cavities from because of its
low coeficent of therminal expansion. There is one alloy, incnel(sp) that
if I remember right has a coeficent near 0. The bad side is the omic
resistance is high so the commercial jobs are cotated with silver.

If I were considering making a cavity and had plenty of power avalible
I would make it out of copper and put it in an oven. I built an oven
for a demo on R factors in insulation that use a 150 watt light bulb
and muffin fan. I wrote a round robin computer program that read a
thermocopule and turned the light and fan on if the temp was less than
50 degrees and off if it was over that. It reached stability in about
3 hours for a 3'x3' box. You could use a lot simpler controler to hold
the temp. If you do this use some kind of Woods metal link that will
melt at 250 degrees or so. Mine got to 300 f when I forgot and left it
on.

The easiest way to get a reasonable amount of power is to use a hybrid power module for the PA. Toshiba makes the M67712 which will put out about 30w for around 80mW in, class AB, 220 -225 MHz. To get from the +6dBm from the transverter to the +19dBm you are probably stuck with a discrete stage, but a BFR96 or MRF571 should be pretty easy.

The power modules are available from RF Parts, San Marcos, CA 1-619-744-0750

I've always thought "MEP" (Maximum Envelope Power) would have been a more appropriate nomenclature for this measurement. Anyway, the meaning of the word "peak" in "PEP" is a misnomer. I think the layman's definition of PEP would be something like "the maximum instantaneous power of the envelope, measured in RMS watts".

>Additionally, the QST article stated that one can not measure CW or
>FM signals the same way, but it seems to me that what's valid for SSB
>is for CW/FM.

The meaning of this statement is unclear. My advice is to ignore it and it will go away.

> Part 97 defines PEP as:
>
>> (6) PEP (peak envelope power). The average power supplied to the
>>antenna transmission line by a transmitter during one RF cycle at the crest
>>of the modulation envelope taken under normal operating conditions.

I've always had a problem with this definition because I don't believe the literal translation
is what the FCC intended. Further, the word "average" shouldn't be in this definition at all.
The average power of a single RF cycle is *not* how SSB or CW RF power is measured - it is indeed an RMS function. Therefore, "average" power of an SSB signal is only relevant when applied to the modulation envelope, and it has no distinct relationship to maximum envelope power. I think the FCC's definition for this measurement is a grammatic goof.

Under Type Acceptance rules, Part 2.985, the output power of an SSB transmitter is measured by injecting a (sinewave) tone, "the level of which is adjusted to produce a radio frequency signal component equal in magnitude to the magnitude of the carrier in this mode."

In other words, the tester would use a wattmeter (like an RMS-reading thruline or thermistor
type) to measure the RF output, which under these conditions will be a continuous wave. The modulation envelope will be flat, and the peak output (misnomer again) will be at maximum carrier level. This paragraph doesn't mention the term "PEP", but I think it's farily obvious that with the output at maximum, the transmitter is producing maximum PEP. Therefore, this procedure tests the rated PEP output of the transmitter. This brings up the point that PEP is not just a theoretical definition - introduction of an AF sine wave at the
balanced modulator produces a carrier, the RMS power level of which is equal to PEP.

>And, am I correct about the true peak power being 2X the 'PEP' measured
>by the above methods?

Yes.

73,

Jack WB3U

1520. SSTV demod advice needed please!

Newsgroup: rec.radio.amateur.homebrew

From: david@pitvax.xx.rmit.edu.au
Message-ID: <3n6uo7$4mv@aggedor.rmit.EDU.AU>
Source record: 113321

I have been intrigued by receiving slow scan pictures with JV-Fax lately, using the simple op-amp limiter interface. So far I've gotten excellent pics from ZL, JA, 6Y (Jamaica) and from around VK of course. A highlight was a noisy but recognisable picture from a GW3. It's a real blast! I'm pleased with the results from a modest 386 PC and a $10 interface.

Now I'm wondering what I can do to dig out the more noisy signals. The limiter I/F has a definate noise threshold - tones have to be well above band noise to decode cleanly.

I'm wondering results with a discriminator type detector compared to the limiter would be similar to results I noted when experimenting with RTTY a while back. Using the limiter I/F and Hamcomm copy was only possible for strong signals, but when using a demodulator with dual filters and a 'slicer' I could copy signals down into the fades.

I have started to collect bits to build a SSTV demod using LC filtering and discriminator. I'll see how it goes as I progress, and will report any success. I see that the trend nowadays is to use pulse width detectors after filtering and squaring the signal. My subjective feeling is that an LC discriminator would work better under noisy conditions as its output is detected and integrated - with the 1/f type detectors the data is fed to the computer without further processing. A step change is as valid as any other data.

I'd appreciate any comments from anyone who has experimented along these lines. I suppose DSP will render both these techniques obsolete eventually - but until I can afford a device I'm happy to spend a few hours winding inductors!

Do you mean the topic of "antennas" is too narrow in focus? I would expect such a topic to catch the interest of quite a few amateurs. Seems to be doing that now, methunks.

Exactly! The rec.radio.amateur.antenna group already exists and
appears to be a perfect forum for the discussion of antennas,
low profile and otherwise.

I've done a lot of SSTV homebrewing and experimenting over the years.
One of my early attempts (described in 73 Magazine December '89) used
the discriminator design with op amps rather than L-C circuits. It
wasn't exactly linear for frequency to voltage conversion and required
adjustment. the output voltage swing was proportional to the input
voltage so a limiter was required anyhow at the input.

Later attempts used digital hardware to measure the time between zero
crosssings (QST Magazine January 93) and the single op-amp limiter
approach (E Z SSTV software from ftp.ucsd.edu:/hamradio/sstv or
ftp.cs.buffalo.edu:/pub/hamradio).

SSTV uses tones in the 1100-2300 Hz range. I found that adding a switched
capacitor filter with bandpass of approx 1000-2400 (to allow for
slight mistuning) made a tremendous difference with the single op-amp
design when interference was outside that range. Of course it
can't do anything about noise within that range.

the external filter didn't help much with my Pasokon TV system because
it already has a bandpass filter in front of the limiter.

Send me your postal address and I'll send copies of the magazine
articles mentioned. I'll even pay the postage to Australia. Always
glad to help another homebrewer. Other people can send me an
SASE with 3 ounces of postage.

Information about SSTV is available on the World Wide Web at
http://www.ultranet.com/~sstv

Let us know the results of your experiments. The major equipment manufacturers have no interest in SSTV so the advances will come from the homebrewers like you.

1526. Focal Point of a Microwave Dish

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-21 00:00:00 UTC
From: CNS@psimemphis.COM
Message-ID: <199504211336.NAA03410@chaos.magibox.net>
Source record: 113327

> I am in need of a formula for the focal-point of a microwave dish. I have a 18" dish that I want
> to put on 10 GHZ. I can't find the formula. If anyone could help, I would sure appreciate the help

Sorry if this comes too late, but I just dug my Satellite
Experimenters Handbook out of storage.

The focal point (f) of a dish is given not by its frequency but by
the physical dimensions of the disk: diameter (d) and height (h).
Height is the depth of the dish (from the bottom of the disk up to an imaginary
string streched from lip to lip). The formula is:

f = d^2 / (16*h)

Hope it helps. Are you using wideband FM or narrowband? I've got
two gunplexor style units that I plan to use for a high speed
(115kb) digital link when I can make the time to work with them.
I've used them for short range (across the room) voice using a 30MHz
FM IF, but I need to build a very-wide band (500MHz) FM IF.

: MHz? The output of the transverter is a 50 ohm impedance. Also the
: article in the handbool says that there will be additional filtering
: required to meet the FCC rules.

The March 1993 QEX has a 100 mW no-tune amp with 16 dB of gain, or
2 dB more than typically needed to drive a Mitsubishi M67712 25 watt
222 MHz power module. A helical filter such as that published in the
20th Eastern States VHF conference would do the job nicely. Putting
everything in separate, shielded enclosures connected with coax is
the easiest way get a really clean signal. Trying to get a clean signal
while stuffing everything in a single box requires either luck, black
magic, or a really sharp radio designer.

> in several different COM programs but can't see a single
> character. I am able to see the carrier detect change states as
> packets are received but can't latch a single character :7(

Baycom style modems don't use the standard RS232 TX and RX lines. The Baycom modems are just that, modems; i.e they don't manipulate the data, just translate audio frequency to on/off.

AX.25 (packet radio) is synchronous - sync flags and checksums for a whole frame (block) of characters; and standard PC serial ports are asynchronous - start/stop bits for each character. So there would have to be some "smart" translation of sync to async between the modem and the PC - which is precisely what a TNC does (and more).

Since the PC has to detect each bit in the received signal, they dont even use the RX and TX data lines. They used the CTS and RTS (or something) since these lines generate interupts for each transition (as apposed to an interupt after an entire character). So the RX and TX aren't even used (except in Baypac modem where they steal 11Vdc to drive the circuitry).

The bottom line is that you wont see anything as a normal serial port. You (and me) wanted to save money but there's still a price to be paid. For me its a price I can (and do) live with.

Besides the Baycom software, there are two other drivers that can work with Baycom style modems: TFPCX (found often with SP6xx) and AX25 (a driver compatible with JNOS-TCP/IP). I think both can be downloaded from ftp.ucsd.edu. I have used both and they work fine (on anything bigger than an 8088!). TFPCX features W8DED emulation and a DED terminal program. Neither of these are straight forward plug and play, though; so if you have questions, I'd be glad to help.

1533. Homebrew Coil Forms

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-21 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <3n9f2g$fgh@nuclear.microserve.net>
Source record: 113334

Hello there,

Just wanted to mention a source of coil forms that I discovered some time ago.

Hardware stores sell a toilet overflow tube that is ideal for coil forms and high power RF chokes. The tubes are made of styrene and are approximately 9-3/4" long after removing the small base assy. Actually, the base has a hole in it's center that's just right for upright mounting with a 6-32 or 8-32 machine screw. The base is not especially sturdy, however, so it's not an ideal mounting method if you're using more than two or three inches of the tube, or if you're building it for a VFO. For large RF chokes, I use a PVC adaptor with two mounting ears and epoxy it to the bottom of the form.

Anyway, the tubes are 1" diameter and have a wall thickness of approximately 0.09" or 0.10", much sturdier than the pill bottles I have sometimes seen used for this purpose. Being styrene (butyrate?), they can distort at the temperatures used in soldering, but are otherwise very stable. If you use a solvent-based adhesive to secure the ends of the coil, the slight dissolving action provides a secure anchor for the wire. Personally, I just spray the completed coil with a couple coats of Krylon or other clear lacquer.

Aside from tuned coils and HV RF chokes, these tubes should also work well for homebrew filament chokes. Cut the tube to size, secure a ferrite rod inside with two dabs of silicone glue, and you have a durable form for winding the chokes. A small hole drilled at right angles in each end will allow mounting the completed choke(s) on nylon or ceramic standoffs.

Incidentally, I have seen these tubes in two varieties. They are both styrene, but one is copper colored and looks as though it may have metallic color flakes in the plastic. I avoid this type for obvious reasons.

Final cost? The tube itself costs about 3 or 4 dollars. Adding the PVC mount, #22 magnet wire, a couple brass screws at the top and a can of Krylon, my last high-power RF choke cost less than $10. In addition, I have enough tubing left for a second choke, and sufficient Krylon for many more.

With care in asssembly (and selection of mounting hardware), the resulting coils and chokes will provide a professional appearance

and long-term performance, all at a much lower cost than their commercial counterparts.

: remarkably useful in many applications.

I bought some at Advance Wire, an electronic distributor that seems to have evaporated in the 5 years since then. Pity, they stocked it in 9 inch rolls and would cut it in any width you wanted on their lathe.

For 3M, it comes from the Electrical Products Division. (Different Divisions have different distributors.) A buyers guide I have lists Anixter, Bisco, EIS, Larsco, Peters-de Laet, West Vally Industries, Coast Air, H. W. Eckhardt and Gourmet Electronics as distributors. (No idea who really stocks it, though.)

Best Bet would be to call the nearest 3M office and ask who distributes Electrical Products. Or maybe 3M has an 800 inquiry number that someone knows.

Type 1181 is the smooth copper with the metal particles in the adhesive
1194 is smooth copper with non conductive adhesive
1245 is quilted copper with partial adhesive coverage for thru conductivity
1345 is a tinned version of 1245

All of them, except 1345 will tarnish over time.

I've just been given one of the 50 MHz AD7008 devices to play with (my
thanks to Colin, G3SBI). The data sheet is very interesting; it includes
a circuit for a two chip Rx using the AD7008 and an AD607 for AM and FM.
Of course, with an AD7008-50 it will be limited to less than 25 MHz,
and the performance won't be very good, but I might try it out for my
own amazement, as one of my maths teachers used to say.

Colin also sent me some info on the "Radware card" which appears to use
a DDS, and connects to a PSA DSP-based sound card. The Radware card plugs
into a PC and, in conjunction with the sound card, constitutes an AM/SSB/CW
Rx, which can also be used as an exciter for a Tx, spectrum analyser for
450 KHz to 30 MHz, and a signal generator. Has anyone got any experience of
this card? I have a feeling that it uses the AD7008, probably in conjunction
with a PLL synthesiser.

The Mini-Circuits RF/IF Designer's Handbook has a lot of info on their
broad-band directional couplers. They aren't too expensive, and it probably
isn't worth "rolling your own". For instance, they have a 1 to 1000 MHz
device for $32.95, one off. They are on (718) 934-4500.

: >rapidly if this sort of regulation is not adhered to. In the 80's John
: Nelson
: >G4FRX now GW4FRX did exhaustive work on this very subject.
:
: Where can I get copy of this work?

Conrad G0RUZ has passed on the references from Short Wave Magazine.
It's also mentioned in GW4FRX's chapter in the VHF/UHF DX Book.

: While I agree that zeners aren't
: usually enough, I disagree that it has to be millivolts to be effective.

Slight misquotation there: I said "hundreds of millivolts" as an
order-of-magnitude, i.e. not "millivolts" and not "volts" either.

Since zeners typically have a slope resistance of up to 10 ohms,
and you need (say) five diodes, then for screen-current swings of
the order of +/-20mA per tube you'll see a voltage swing of +/-
several hundred millivolts on a two-tube amp. It doesn't help to
use a smaller number of higher-voltage zeners, because their slope
resistance is higher and you find that the overall regulation is
about the same. In other words, zeners are marginal, as Tom says.

: I asked a couple Engineers at Eimac and they are puzzeled about the
: millivolts too as long as there is some dynamic regulation from a cap.

As noted above, "millivolts" is overstating the requirement,
so I daresay Eimac would have been puzzled :-)
The cap is a good idea, but it needs to be quite a high value -
100uF or more - to have much effect on dynamic regulation for SSB
speech.

By the way, GW4FRX did discuss his results with Eimac, who at that
time had no comparable measurements of their own.

: What I found here was that if the screen was held within a percent or so,
: the IMD from typical radios (only -30 to -35 dB on the ones I tested) was
: much worse than the tube. I wonder why this difference? I also found a

: cathode resistor for negative feedback helped substantially.

Were your measurements with 4CX250s and 350s, Tom?
These tubes are far more sensitive to dynamic screen voltage than are beam tetrodes in general. For example, you can get excellent IMD results from 6146Bs without any attempt at regulating the screen voltage - in fact it's customary to use a 100ohm series resistor in each screen feed! But you can't do that with 4CX250s or 350s... well, you can try, but your neighbors on the band will notice the difference.

To be fair, the original question way-back-when was about a VHF amp, and the lower background noise at VHF does call for a higher standard of signal purity than at HF, where IMDs of -30dB may vanish down in the crud and QRM. For HF SSB, maybe I'm being over-critical.

Zack KH6CP/1 asked:

: What would you recommend in place of a two tone test for better
: measuring the distortion products? Perhaps something along the
: lines of an effective bandwidth measurement with a "standard"
: voice waveform?

Yes, I think so, because IMD under dynamic voice conditions is what other band users are concerned about. More specifically, we're concerned about *peak transient* levels of IMD, a.k.a. "splatter". At VHF/UHF in particular, we're also concerned about the levels far out from the signal itself, and how rapidly they die off as you tune away.

We definitely need something more realistic than the conventional two-tone tests, which are static and usually only cover close-in 3rd and 5th order IMPs. No hi-fi lab would dare to test an audio linear amplifier in such a naive way!

A very simple technique requiring no testgear at all is to have a local friend tune across your SSB signal using a RX with a known good dynamic range, and tell you how many kHz either side before your splatter disappears into the noise.

For all its simplicity, that talk-and-tune method goes directly to what you need to know about your transmission quality.

Since the spurious-free dynamic range of a good VHF RX can be well over 90dB, that's how far down from PEP you need to be looking in laboratory measurements as well.

To adapt this to reproducible laboratory technique, one possible method would be to make a very narrowband slow sweep through the SSB signal,while a digital voice recorder reads from the ARRL Handbook in an endless loop. The sweep needs to go as far out on either side as necessary for the splatter to disappear completely.

You'd need a storage spectrum analyser in peak-hold mode to save and plot the *highest* recorded IMD level as a function of frequency.

It would need a very good analyser to achieve the dynamic range required, and it might be better to use a dedicated single-conversion 'front end' with a high-level mixer and narrowband IF filter. Say you use a 250Hz IF filter; you could then leave the analyser tuned to the IF frequency, in peak-hold mode, and tune the LO to step across the signal in 250Hz increments.

OK, I'm sort of making this up as I go along. Pause for comment: does it make sense to test our SSB transmitters in this way?

> Does anyone have experience of using the synth chips by National, or Fujitsu. I
> am using these Ic's but finding problems with the drive level, or miscounting
> due to harmonics.

The 1501 chip MUST have CHIP (as in SMD) capacitors as close to the
IC pins as possible. This is particularly true of the phase comparator
output, the lock detector output, and the VCC lines. I recently
had a difficult time using this part at 550MHZ until I switched over
to chip cap bypasses. By the way, this also improved the sensitivity
at least 10dB, and the part then was stable and met its published
specs.

Being an enthusiast of long-wave communications, wondering if anyone on the NET is still participating in the 160 - 190 KHz band per FCC part 95 (I believe). Some years back there were alot of beacons and experimental work happening in this band, mainly driven by HAMS even though a ticket is not required.
I am interested in hearing from anyone still interested in, or active on this experimental band. I am located in the San Francisco Bay area. Also at one time there was a newsletter published by someone (a HAM) for projects, equipment and other activities for the "LOWFER" gang.

Any contact please --- Thanks --- Bob // N6MTU.

> -- KD6PAG (networking old-timer and RF newbie)

Analog Devices have two chips - AD7008 and the new one AD9955.

AD7008 has 32-bit phase accumulator and 10-bit DAC converter on chip.
20MHz output.

AD9955 has also 32-bit phase accumulator, 12-bit sine digital output,
no DAC on chip. Driving freguency 100MHz typ., 85MHz min.

Qualcomm has Q2220, Q2230 and flagship Q2334 with _two_ DDS
circits in one chip with the noise reduction circuit
(noise due to the phase truncation). To my knowledge neither
Harris nor AD have that. Also FSK, MSK and PSK are possible.
There are some good ideas of the second order dithering in conference
proceedings from 1994 and 1995.Qualcomm also offers evaluation boards
with DDS chip and DAC on theboard. I found their idea of PLL driven by
DDS output very interesting.(850-1750MHz with <1Hz steps - application
note AN2334-4).

>understand why a *peak* measurement is made by reducing the peak
>voltage to a .707 value.

Look at it this way. Compared to the carrier frequency, the modulating frequency is extremely low. That means that from one RF cycle to the next, the peak amplitude--and thus the RMS amplitude--of the signal doesn't change much. But if you look at the signal for long enough, you'll see the RF cycle amplitude changing with the modulation. What we are looking for is the largest-amplitude RF cycle during the period of the modulating signal. We then calculate the RMS power for that largest RF cycle, and that's the PEP. Since we are calculating an RMS power, we need to do so using an RMS voltage. That's where the .707 comes from.

>Even accepting that PEV * .707 is determining
>the *average* value instead of the RMS value (for RF) , as stated in the
>ARRL Amateur Radio Handbook, I still don't follow the reasoning.
>Using the above equation, it appears that a 1500W PEP output amplifier
>would have to be capable of outputting 3000W PEP on the *true* peaks
>in order to not "flat top" and produce excessive distortion products.

No, a 1500-W PEP amplifier has to output 3000 W *peak,* or instantaneous, not PEP. But you have to be a bit careful here. "Instantaneous" power is something of a conundrum.

>Additionally, the QST article stated that one can not measure CW or
>FM signals the same way, but it seems to me that what's valid for SSB
>is for CW/FM. Part 97 defines PEP as:

I don't think it said quite that. It said the PEP of a CW transmitter is just its key-down RMS output power, and for an FM transmitter it's just its RMS output power, which doesn't vary. In all cases, the PEP is the power in the highest-amplitude cycle of the RF signal. For CW and FM transmitters, the amplitude is constant (and easily measured).

>> (6) PEP (peak envelope power). The average power supplied to the
>>antenna transmission line by a transmitter during one RF cycle at the crest
>>of the modulation envelope taken under normal operating conditions.

>O.K. Accepting that the 'average power during one RF cycle at the crest
>of the modulation envelope' is actually ((PEV * .707)^2)/50 and not

>((PEV * .636)^2)/50 why would CW/FM be treated differently than SSB?

For power, "average" and "RMS" mean the same thing (over one cycle).
For voltage and current, the two terms mean different things.
Specifically, for voltage and current, you get the average by
averaging the instantaneous values of voltage or current over a cycle.
You get the RMS value by average the *squares* of the instantaneous
values and then taking the square root. For power, you calculate
average/RMS by taking the average of the product of voltage times
current, then taking the square root.

If you were to go through the math for that, you would find that
another way of getting the RMS (or average) power is to multiply the
peak voltage by .707, the peak current by .707, then multiply the two
resulting values. That's the *reason* why the RMS value of voltage or
current is 0.707 times the peak: because that's the value which makes
the product of RMS voltage time RMS current equal to RMS power.
(The .707 is only valid when the waveform is a sine wave, by the way.)

>And, am I correct about the true peak power being 2X the 'PEP' measured
>by the above methods?

The peak power is 2x the PEP. But that's not particularly useful
information. Values such as tube dissipation ratings are concerned
with RMS power, not instantaneous values.

>Anyone care to clarify this for me?

Hope that helps.

"Instantaneous power" can't be an RMS value, since RMS values are
time-average values.

"RMS power" and "average power" are the same thing when you are
talking about a single cycle of a sine wave. That's why the FCC's
definition is technically correct.

Yes, I realized too late that this was a poor choice of words. I probably should have said "the RMS power of the envelope at maximum modulation". Then again -

>"RMS power" and "average power" are the same thing when you are
>talking about a single cycle of a sine wave. That's why the FCC's
>definition is technically correct.

Yes, again. In fact, I'd go so far as to say that "RMS power" is a nonsensical term, because technically, RMS Volts x RMS Amperes = Average Power.

Anyway, thanks for pointing this out. Gotta stop posting this stuff at 4:00 in the morning . . .

From: agtss@tibalt.ab.ca
Message-ID: <3na765$lhl@tibalt.supernet.ab.ca>
Source record: 113353

Hi,

I'm looking for some information on directional couplers. I've read several articles and texts but am still left with a several questions.

1. What value should a designer pick for Zoe or Zoo and why. I realize they are related and to the system Zo [Zo = (Zoe *Zoo)**1/2], but I can't find anything to tell me what values to use and why. Given one has a frequency BW, and degree of coupling in mind it seems to me you still need Zoo or Zoe before you have your coupler?

Any ideas?

2. Is there any good literature on very broadband couplers (10 Mhz to 1000 Mhz.) In the 60's HP designed a coupler (HP778D) which used a tapered line from the main line to achieve a very broad bandwith. Is there any published information on this? Or given I only want one, does anyone know where I can pick one up without a major expense.

Any help or suggested references would be deeply appreciated!

I need to know a frequency that can be used for a low power transmitter for "home" use, like a remote control or whatever, above 800 Mhz. I want to put out up to 300 mW, but would settle for 100 mW.

I really don't know where to look, so if you would please tell me where you got your data, it would be appreciated. I looked through my "scanner" listing and also the ARRL manual with no luck.

This is for use both in the USA and elsewhere, so it would be nice to have a freq that is open everywhere. (yea I know, good luck)

It needs to be "approved" by any local government, since it may become a product.

Please write me via Email, so as to not tie up the net, thanks!

It's getting to the point that in order to live somewhere these days, it's necessary to waive all kinds of rights and otherwise regular privileges, including those pertaining to antennas that are normally at least partially protected by PRB-1. Condo and apartment living is becoming more common as single family dwellings are becoming less affordable and an increasing number of amateurs are being subjected to these severe restrictions.

The issues that might be addressed go beyond just a type of antenna. A rec.radio.amateur.low-profile newsgroup can deal with and provide help with both "stealth" antennas and the issues that make them necessary.

The BIG problem with trying to look at data on the serial port is that, with BAYCOM, it is not using the serial port in a serial manner. Serial Port pins 2&3 are the TX & RX data pins (and thus are what are used by your typical Com Port programs) but are not even USED in the BAYCOM hookup. The pins are actually monitored and controlled directly by the baycom software in a manner that is not comprehensible to the "normal" serial port program. The interrupts and everything else is completely ignored. This is why you can't see the data, it is not appearing on the pins. If you have machine language capability you can monitor activity on pin 5 (normally CTS on db25 connector) or pin 8 on a 9 pin connector... but even if you can read data from those pins somehow it will be just garbage... unless you can cobble up the AX25 protocol to decode it .... which is what your baycom software is doing already. I believe if you read your baycom docs you can set your monitor capability in the SCC.INI file to display all characters on your F10 monitor screen which allows you to see all the scrimshaw stuff coming through your modem.

1565. Having a problem my my CAT, can you help???

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-24 00:00:00 UTC
From: mckee@fc.hp.com
Message-ID: <3nfgqr$dkf@tadpole.fc.hp.com>
Source record: 113268

Greetings all:

I have just finished a quick and dirty (and at the moment not functional :-)
homebrewing project. I have a Yaesu FT747GX that I wanted to hook to
my computer using the CAT (Computer Aided Transceiver) interface. In
order to gouge you for $80 or so, Yaesu decided to make the serial output
TTL level, not RS-232 level and then get rich selling level converters.

Using a MAX232CPE (a single 5V IC designed to do just this), I build a
small level converter that takes RS-232 in and spits TTL out in one
direction (to the radio) and does exactly the opposite thing going the
other way.

Looking at the circuit with my 'scope seems to indicate that it is working
fine. Unforunately, I'm unable to control the radio with my PC.

I wrote a small program to send data to the interface as documented in
my manual (port set to4800:8,n,2), and once again, the 'scope shows it
to be working. When I send commands to the radio, the <CAT> indicator
on the front panel lights up, but I cannnot get it to do anything else.

I have sent it all possible commands, just to see if I was having a
problem with understanding the manual, but it did nothing either (Since
command blocks are 5 bytes long, I just sent 255 groups, each consiting
of the same character repeated 5 times). Since there is a "up 500K" and
a "down 500k" command, I expected to see the indicator change at some
point through the cycle.

So, has someone who as successfully done either half of this (built an
interface, written control software) give me a hint??

73,

de N0MTA, Bret "so close, yet so far" McKee

>If that's the case, I'd better stop running 1000 watts output on CW.

>Mike, K0TER

Peak envelope power is peak envelope power. Period. On CW/FM, it's

peak voltage times .707 to give you RMS voltage.

Then calculate power from there. (E^2 over R).

On SSB, they are just taking the maximum peak voltage, and (somewhat
arbitrarily) taking that as a voltage that you multiply by .707 from
which to calculate the power.

thus, a carrier of 20 volts peak (40 volts peak to peak) comes to 4 watts PEP
into 50 ohms. A SSB signal with the same maximum value is also 4 watts PEP.

That's how it's done, folks :-) .

1570. How do DTMF decode chips work?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-24 00:00:00 UTC
From: rn@cs.brown.edu
Message-ID: <3nglak$c7j@cocoa.brown.edu>
Source record: 113273

I would like to find out precisely what heuristics DTMF decode chips use to do accurate detection of tones. I've been playing around with DTMF detection in software (doing real-time FFTs on a digitized audio stream and checking the frequency spectrum for energy at the appropriate frequencies), but I'm having difficulty striking a balance between falsing (detecting tones that aren't there) and missing tones that really are there.

My experience with various DTMF decode chips has been very good: they rarely seem to false yet they pick up what sounds like even very faint tones. Does anyone know precisely what they do? Do they simply check for energy at the appropriate frequencies (plus or minus some tolerance), or do they do something more sophisticated such as trying to look for energy at certain freqs and no energy elsewhere? My goal is to do as well in software as these chips do in hardware, but the simple approaches have so far failed.

Rob Netzer, KD1TS.

Some of the DSP chip manufacturers have excellent application notes
for robust DTMF detection. I remember seeing the AT&T
Microelectronics and TI notes, and probably Motorola and Analog
Devices have them as well. A good bookstore would have the TI
or ADI collection-of-apnotes books.

From: au156@yfn.ysu.edu
Message-ID: <3ngv1p$98d@news.ysu.edu>
Source record: 113275

The recent discussion here regarding peak envelope power engendered
by the May 1995 "Lab Notes" column has resulted in some pretty
substantial mangling of proper definitions and concepts associated
with alternating current.

One of the crucial points is that there is NO accepted standard
definition of "RMS power." This is a misnomer, no doubt fueled by
almost universal misuse in advertisements for consumer audio equipment.

The correct term is AVERAGE POWER. Besides just terminology,
the underlying concept of the distinction between RMS current
or voltage, and *average* power is very important. If this is clear,
then some of the confusion concerning things like PEP will lift.

Quoting the ARRL Handbook (1987 ed.) in the Electrical Fundamentals
chapter under AC Waveform Measurement: (<> denotes "not equal")

The relationship between ac voltage, current
and power follow:

RMS voltage x RMS current = average power <> RMS power
....
RMS power is a mathematical curiosity only and has no
physical significance.

So a previous writer's assertion, while reflecting the common
usage of the misnomer "RMS power", is nevertheless technically
incorrect:

>For power, "average" and "RMS" mean the same thing (over one cycle).

Another person questions the language in the FCC rules regarding
PEP measurement:

>Part 97 defines PEP as:

> (6) PEP (peak envelope power). The average power
> supplied to the antenna transmission line by a
> transmitter during one RF cycle at the crest of
> the modulation envelope taken under normal
> operating conditions.

>I've always had a problem with this definition because I don't believe
>the literal translation is what the FCC intended. Further, the
>word "average" shouldn't be in this definition at all.

I hope that it will be clear from the foregoing explanation of the
meaning of average power that this definition is perfectly correct.

For those that would like to know more about RF power measurement,
I would recommend careful reading of the appropriate
sections of the ARRL handbook.

>
>Any ideas?
>

The relative values of Zoe and Zoo determine the amount of coupling. Most texts assume that the coupler is sized for maximum transfer, which occurs when the coupling line is an electrical quarter-wavelength. If you want to evaluate a particular geometry, the following equations may help.

I assume you have a means of calculating Zoe and Zoo from physical dimensions. You also need the wavelength, lambda, (electrical, not free-space) and actual length (same units, of course).

lambda = Veff / frequency
theta = length/lambda * 2*pi
k = (Zoe - Zoo)/(Zoe + Zoo)
Coupling, dB = 10*log10((1 + (1 - k^2) * 1/(tan(theta)^2)) /k^2)
Zo = sqrt(Zoe * Zoo)

I'd suggest setting up a spreadsheet so you could enter Zoe, have it calculate Zoo for the desired value of inline impedance, Zo, then calculate the coupling value. Iterate until you get the desired result.

>2. Is there any good literature on very broadband couplers (10 Mhz to 1000 Mhz.)

>major expense.
>

Low-loss, multi-octave couplers are tough to homebrew. Particularly down to 10MHz, where a quarter wavelength is pretty long. If I remember correctly, the HP778 is around 2foot long, and only goes down to about 100MHz. If you can tolerate some inline loss, a transformer based hybrid would be feasible, although limited in terms of power-handling.

If you are just looking for something in the small-signal range, for swept frequency measurements, etc., they are available from Mini-Circuits, amongst others. Alternatively, a few 50ohm surface mount resistors and a ferrite balun can give excellent results over the 1MHz - 1GHz range albeit with about 6dB loss.

Good luck,

The standard technique for decoding DTMF using DSP is the Goertzel algorithm.
It is related to the FFT (it's much simpler and can process samples on the
fly), and is described (with source code) in the Analog Devices book Digital
Signal Processing Applications using the ADSP-2100 Family, published by
Prentice-Hall. You can find the code on ftp.analog.com, I think.

The degree of coupling dictates Zoo. For tight coupling (3 db hybrids) you need
a relatively low Zoo. Frequently, this is impractical, so two 8.44 dB. hybrids
are used in tandem to get 3 dB. For loose coupling like the 778D, Zoo would
typically be rather high, and Zoe would be close to 50 ohms.

I've never seen a 778D at a swap meet (if I did, I would have snapped it up).
Your best bet is to try to find a Narda equivalent with bent, spun, or broken
connectors, get it cheap, and repair it. I've seen many Nardas needing repair.
If you want to read about how to design them, get Matheis, Young and Jones's
Handbook and read Bud Crystal's papers on the subject in the 1964 to 1968
IEEE MT&T transactions.

Thanks Joe,
I am using the National IC from 45MHz to 470MHz, but find that at the low frequency it seems to require an enormous drive level 5V p-p, and if the signal is not absolutely clean of harmonics, then it miscounts, just a little, so that with a 12.5kHz reference it is about 3kHz off frequency. You can see it miscounting by the jitter on the divider monitor output. I am using good SM capacitors on the supply, but have not tried decoupling the phase and LD outputs, this I will try and report back!
There is no spec. quoted for min rise time/slew rate of the clock input, I suspect this may be the problem, and I can't seem to get any more info out of National. The National IC seems to be only available as SM, does anyone know otherwise?
Sorry for the Typo in the thread.

As for one who has had to deal with using "hidden attennas" I feel this newsgroup would be highly useful. As for those who might not feel this way, dont knock it until you have had the :pleasure" of working Alaska or Hawaii using 30 ga magnet wire for your attenna. The contacts at times my be rough but just as rewarding as any contact that can be made using Full size attenna's.

>units and CONdos as well as QRP fans (even though I run about 30W ... :).

I'm undecided as to how I'd vote for the proposed group, but the above suggestion is an entirely different topic. I live in an apartment, and have done so for virtually all of my time as a ham (the other time was in a duplex with a small yard, so it still sort of applies). I haven't run much QRP. In fact, the closest I ever really came to QRP was when I was using a loaner HF rig w/ my 4.5 Amp power supply---I had to limit the transmit power to < 10 watts to avoid going beyond the power supply's limits. Even the 30m xcvr I built once ran about 15 watts....

In my current apartment, I have full-sized dipoles folded along the (wood) stairs (like many buildings along the coast, and particularly here on the island, this apartment building is built on stilts to help protect it from storm surge in a hurricane/himicane). When I run voice (rare) or cw, I run a full 100 watts. When I run AMTOR/PacTOR, my HF rig automatically cuts the power down to about 50 watts due to the high duty cycle.

Do I have RFI problems? Nope. I did, briefly, when a neighbor had a quick-disconnect cable between his TV and VCR, but that took a few seconds to fix, and has never re-appeared.

If anything, though, I think a QRP group would be more fitting than a sub-group for restricted space antennas, which, IMHO, is probably ok right here.

Just my $0.02, all IMHO, of course.

Later,

IMHO this is a much better idea then the current name. My feeling is
there is a much broader base of users for qrp, and it could include the
low profile people also, since they seldom run 1000 watts.

>equipment or removed from equipment, mismarked, experimental, etc

Hi Kerry,

Not to rain on your parade, but the devices you're looking for are in high demand
in the MMDS/ITFS industry. We use GaAsFET's working from 2.5 - 2.7 GHz,
at power levels from 10 to 30 watts, and they're very expensive.

Additionally, the only devices of this type with any record of dependability are
manufactured in Japan (Fujitsu, Hitachi etc.). At one time, there was a company
on the east coast making them, but (I've been told) the yield was very low.
I believe they went out of business a few years ago.

Anyway, the devices we use cost about $100 - 300 each, and they're like
gold. Some of our higher-power (100 watt) television transmitters use thousands
of dollars of these FET's.

Good luck and I hope you find something, but you might want to consider a
different means of generating this power for now. On the other hand, if
you come across a sizeable stash of these at something less than the
above-mentioned prices, let me know. Maybe we can work out a good
deal for both of us.

73,

Jack WB3U

Oops! That's 500kHz, not 500MHz. Sorry for the fat fingers! I'm
using the Motorola MC3356 with on-board IF mixer. Motorola does
have a 12MHz bandwith chip that might work for 10MHz signal; (imagine
having a 10BaseT link).

: 1,000 Watts CW Output??? Isn't it 1,000 Watts DC Input?

: Did I miss a rule change?

: Jack WB3U

Yes, you did. Quite a long time ago, as a matter of fact. It was
changed from 1000W DC input/2000W PEP input to 1500W PEP output.

part 97.313 says:
(b) No station may transmit with a transmitter power exceeding 1.5 kW
PEP.

Section 97.3 (a) (6) states:
(6) PEP (peak envelope power). The average power supplied to the
antenna transmission line by a transmitter during one RF cycle at the crest
of the modulation envelope taken under normal operating conditions.

Note that it says 'supplied to the antenna transmission line by a transmitter'
or, output power.

Of course part 97.313 (a) still applies:
(a) An amateur station must use the minimum transmitter power necessary
to carry out the desired communications.

On my part, this is all discussion. I haven't had my amplifier on the air
since December. Haven't needed it.

Thanks to all of you for your interest in my original question.

|>other way.
|>
|>Looking at the circuit with my 'scope seems to indicate that it is working
|>fine. Unforunately, I'm unable to control the radio with my PC.

What exactly do you see? Do you see your send data? Do you see an echo
coming back from the 747? The 767 CAT echoes back the command received
within 5-20 ms. Are you seeing anything at all come back from the 747?
After the radio echoes the command, you may need to send an ACK command
to the radio to acknowledge that it got the command correct. Again, this
is how the 767 CAT works. Note that each CAT implementation is different
(thank you Yaesu :-( ) The FT-1000 does not echo the commands or expect
an ACK.

I also seem to recall there being some timing issues, i.e., if you delay
too long between characters, the radio won't recognize the command.

Good luck and keep plugging away at it. It should work as I basically
did the exact same thing, i.e. built a level converter using the
MAX232CPE chip, and it works like a champ.

SMART CARD READER / PROGRAMMER
PIC 16C84 PROGRAMMER

An extremly versatile unit to enable the user to Read and Write to all types of ISO 7816 Smart cards AND Program PIC16C84 devices.

The unit requires an IBM PC computer and a power supply of between 15 and 20 Volts AC or DC.

Fully ISO 7816 compatible (the standard used in many TV access cards, Phone cards and GSM Mobile Phones)

The Smart Card ISO7816 Reader / Programmer software can use external data files to write to the card and "log" the answers back to a disk file of your choice. Data parameters can be changed from within the software. Single or Multiple bytes can be sent via the on screen "Send Buffer" editor, any response from the card will be displayed in the "Received File" Window.

The PIC84 programmer will allow the user to program the chips in circuit via a 5 pin connector on the main board, the unit can also program the common 2Chip and 3Chip ISO7816 card emulators commonly used in the Satellite TV industry.
With this unit it is possible to program in .BIN or .OBJ format

The unit is supplied with powerful operating software to enable the user to Read / Write / Copy and Examine / Change any or all of the internal memory on the 2 and 3 Chip ISO7816 type smartcard emulators.

The unit mesures 9cm X 6.5cm approx, is double sided throgh plated and solder masked, because of the high standard of manufacture we have no problem in offering a 1 Year parts and labour guarantee with every unit.

The unit is supplied with all operating software and "useful" data on various subjects relating to Smart Cards.

The complete package (hardware / software and data) costs only:-
79.95 inclusive of postage and packing to UK
85.00 inclusive of postage and packing to EEC (outside UK)
other destinations 85.00 + DHL costs or Royal Mail swift costs.

Source record: 113304

Actually the degree of coupling determines the difference between Zoo
and Zoe. For very weak coupiing Zoo and Zoe are close to Zo. Extreme
example, imagine no coupling at all. Then both lines are Zo and Zoo=Zoe=Zo.
3 dB coupling is non-trivial, but you can buy them readily. They are
called 3-dB hybrid couplers. The principle use is power splitting/combining
whereas the weaker couplers are used for power measurement and impedance
measurement(VSWR).
Broadband couplers are indeed an art if you want constant coupling factor
over a wide bandwidth.

1604. Building or Buying a Phone Patch

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-04-25 00:00:00 UTC
From: donert@tdbank.ca
Message-ID: <3nivpn$rh@inforamp.net>
Source record: 113305

I am looking for a phone patch design that provides a line level output signal of the remote caller as well as a line level input for the local caller.

The purpose of this patch is to interconnect an audio mixer with a telephone. I would like to be able to build such for under $100. Are commercial units available in this price range?

A friend suggested that this kind of equipment is plentiful in amateur radio land.

Hello everyone,

I am wondering if there is any information available on the company S.H.F. Microwave Parts Compnay. They are located in La Porte IN suppposedly. From what I can gather they can supply microwave parts like gunn oscillator parts along with some other related hardware for the X and K bands.

I have their address but there is not an address listed there. I would really like to talk to these people so that I could get a current flier from them and see what the prices are and also what is available from them.

I think you should be able to make it work OK but be careful about the
levels you pick for the transmit direction. 3 X 50MHz isn't too far from
2M and you will probably have some of that component to filter out.

I am thinking of building a small transmitting loop per Ted Hart's design
in the ARRL handbook. I have never talked to anyone on the air that
was using one. Would appreciate if those with on-the-air experience would
compare these antennas with commonly used ones (such as dipole or vertical)
for DX use in a restricted space application.

Steve Johnson,
N2FT

P.S. Also interested in possibility of using a two or three turn loop. Any takers?

>the electrical signals into the corresponding text?
>

I built the Morse/PC interface that was in QST about 3 months ago. On the receive side it is a phase lock loop that locks onto the audio tone from the BFO. On the send side it just drives the key input of a transmitter. I have a small relay installed for isolation.

The PC software (download from the ARRL BBS) assumes that the time ratio of dits to dahs to character spaces is correct. Any time that a received dit varies from the duration that it is currently expecting, then it adjusts the time partially in that direction, thereby constantly adjusting the timing to the characteristics of the received signal. When a character space is detected then the received Morse pattern is used for a table lookup.

The transmit side uses the last receive timing and reverses the table lookup to switch the keyer in a Morse code pattern.

It works well on a fairly good signal. The ear works better on a weak signal.

I'm looking for a reasonably priced audio output transformer, for an amplifier restoration project. It's got to be a good match to a pair of 6L6GC tubes in push-pull configuration, and ideally will have secondary windings/taps to match 4, 8 and 16 ohm speakers.

If anyone has such a beast kicking around in their junkbox, I'd appreciate hearing from you. Suggestions of where to buy one would also be great. Otherwise, I'll have to bite the bullet and buy new from AES; a bit more than I'd hoped to pay!

Shade,

I think the best idea is to remove the battery pack from your hand held and
store the set in a sealed die cast box. Hopefully your monitor will then
have a chance to recover from the RF shock.

Never heard of it, but seems to me the equipment would consist of a loooong
antenna, low pass filter (about 15 Hz), and an audio amplifier.

Personally, this sounds like a lot of trouble to me. My 50' mast in the
backyard receives lightning on a regular basis.

And some wisdom from davev@atkc.COM (Dave van De Kerk)

:As an apartment dweller and a radio amateur interested in
:HF CW, this group is exactly what I am looking for. It is
:not just limited to discussion about antennas. Topics I
:forsee include:

* dealing with landlords and covenants
* TVI and RFI to others
* TVI and RFI interference to your operation from
others.
* negotiations with neighbors on operating
* strategies for HF operations to stations out of
your own state on extremely ineffecient antennas
and low power.
* RF safety in extreme proximity.
* operating satellites with low profile equipment.
* Urban emergency operations using rapidly deployed,

improvised installations.
* Care and feeding of the older, less expensive
equipment us "stealth" operators seem to use.
* Installation of the shack in very space challenged
areas that the XYL or other significant other
lets us use.
* How to get a good ground on the 27th story.

:None of those topics are related to antennas. Of course, I
:also would include:

* help with making an HF antenna that is nearly
invisible and gets out.
* invisible commercial HF antennas.
* help with making a VHF or UHF antenna that is nearly
invisible and gets out.
* invisible commercial VHF/UHF antennas.
* antenna modeling
* antenna installation tips and hints

:For those of us who are not rich, never will be rich, and have
:less space to work with all the time, this group looks wonderful.
:Please vote yes.

Low-profile ham radio is an extremely challanging and highly specialized
pursuit of the Hobby. As quoted herein, there are a myriad of subjects
that need to be cussed and discussed. I have been a fan of operating
my HF station under all kinds of conditions, mobile and portable and
I highly endorse this newsgroup. Just because some of us are fortunate
enough to have full-size dipoles and gain antennas NOW, remember that it
wasn't always this way and that there are others who need this exchange of
specialized information to learn and experiment to improve their skills
and talents in this area.

If the Net can support 8,000 + newsgroups, would one more really make a
difference? Next tine you take a trip, try taking along a 40M QRP
transciever and some magnet wire and try to make a contact or two.
This kind of activity can be great therapy after a day full of snake-pit
business meetings. Try working some of your buddies back home from your
Company-paid hotel room. Its a lot of fun! At least if you are not into
trying this, you may find it enjoyable and entertaining to read the experience
of others. Remember, the basis of our Hobby and license is EXPERIMENTATION!
With the proliferation of consumer-grade transcievers and "rice rockets"
which are not generally user-servicable, can any of you tell me any areas
of research and experimentation other than antennas and operating under
low-profile conditions? So, loosen up you detractors, and think before
you condemn! No one's twisting your arm to read or participate in this
proposed newsgroup. You probably wouldn't have much to contribute anyways!

Donning asbestos suit! Fire away! But no replies until after Dayton!

?

The reason for a group is to be if there will be sustainable discussions. This group is being proposed has a *lot* to do with rec.radio.amateur.antenna with a bit of the inflamatory rec.radio.amateur.policy thrown in to boot. If the existing group structure can support discussions proposed in the group, then one should ask `Why do some people feel the existing group is inappropriate for this discussion'.

>Next tine you take a trip, try taking along a 40M QRP
>transciever and some magnet wire and try to make a contact or two.

Hi,

I've always thought it would be great if one could make a really small direction-finding unit that would be the size of a small calculator, including the antenna (something like James Bond would use). I'm curious if anyone has ever tried making such a unit, and would like to share their experiences with it. I've never gotten beyond the "thinking about it" stage myself. I do think that a ferrite loop, such as the ones found in old AM pocket radios might have a good chance of working. However, that would only probably work at frequencies of several MHz, and the transmitter would have to have a big antenna to get the signal out. Anyway, I'd appreciate any comments.

A rather old book, _The_Amateur_Scientist_, is a collection of articles
from the series in _Scientific_American_ magazine. They had a construction
project for a thunderstorm warning receiver that measured the ratio of
static pulses at 2 or 3 frequencies, it also measured the voltage gradient
a few feet above ground. The thing used tubes, but the concepts should
help you out. Good luck in the library!

If you want a matching Tx, I've just seen an advert for a Breitling watch
with a built-in beacon on the distress air channel. There is what looks like a
little telescopic antenna that pulls out from next to the winder. Of course,
you shouldn't use this frequency.

I presume you meant 8 KILOhertz. A lot of work was done before and during WW2 on long-distance storm detection using radio direction finding at frequencies between about 5- and 20-KHz.

It works fine over oceans, but not well over land. It is true that individual lightning crashes can be detected over distances of several thousands of miles, e.g. storms near Hawaii can be spotted from the Philippines. Propagation over land causes phase distortion that messes up the DFing.

The USAAF Weather Service established several networks of 4 RDF installations, each, in 1944-45. The system was called "Sferics". It worked reasonably well and gave accurate information. I know because I spent a number of months flying on a reconaissance aircraft that covered almost the whole Atlantic, verifying that the thunderstorms were actually where they were supposed to be.

I used one in a dorm room for a couple years when I was a student (before I found out that the bunk beds were almost perfectly tuned to 6M, which is another story altogether). Basically, you can't hope for the performance of a good vertical, but it's still surprisingly effective. In my case there was no possible way for me to put up a more bulky antenna, and the loop served very well considering the effort involved to construct it and the fact that it took no space to speak of. The one I built consisted of 18 AWG magnet wire scrapped from a motor, wound around a hula hoop, with a matching network. It was described in a late 1950s issue of QST somewhere.

Don't know about a pentium, but I do recall _many_ years ago when these
things were not so plentiful, making point contact Ge transistors. It needed
a steady arm (!) but quite a few worked. I did get one to oscillate quite
well enough to make a simple transmitter, the odd micro-watt I suppose.
Kind of nostalgic I suppose, but we've come a long way since then...

Don't forget the possibility of using a video IF SAW filter - 45.75 (NTSC)
or 38.9 MHZ (PAL).

I agree - two IF's will be required in this design for good image rejection,
unless the builder has room for resonant cavities the size of trashcans.

Regarding the 1st IF, I think this will require basically discrete circuitry.
maybe with a few MAR's for higher "gain density".

Beginning to look at it myself. I recently obtained a RS Cellphone and have the service manual on order. The processor is a simple RCA 1800 series part and the handset is connected via a DB25. The biggest problem I can see so far is most of the RF parts look like they may not move well.

Definately would like to experiment on the 33 cm band (902-928), and this seems the best vehicle so far to do this.

Let me know if you have any success, and I'll do the same.

I have also sampled the signal at 2400 hz, but i've seen the specs for a
comercial decoder claiming 2-3 miles resolution per pixel. By my
calculations and through observing pictures produced by my decoder
indicate 3-4 miles per pixel. Thanks for your response. Steve.

Anybody got a phone or address for Circuit Cellar or similar outfit. My beloved Crown D75 audio power amp gave up the ghost so I'm getting it revamped and then plan to use it for something else. However, that would leave my Mac with no way to drive the Bose Roommates :-)

Rather than blow 70 bucks for piece-o-sh** bottom of the line Radio Smack amp, I'd like to order a basic line-in, speaker-out, volume control stereo amplifier kit.

E-mail replies would be preferred. Thanks in advance. I know this really isn't an amateur homebrew related post but I couldn't locate another appropriate homebrew newsgroup.

There was an issue of Scientific American, back when C.L. Stong was
still writing the _Amateur Scientist_ column, which detailed how to make
point-contact devices in your kitchen oven. I tried it in the early
seventies and I was getting massive contamination problems and consequently
high noise floors, but I was getting a gain as high as fifty or so. It
was a whole lot of fun.

Hmm.. wonder what it would take to do the Mesa process in your kitchen?
Photoetching is no big deal; you might even manage to use silkscreen resist.

Like, uh, the rules have undergone significant changes over the
last 10 years. Maybe you ought to go buy a recent copy and
read them, since amateurs *are* supposed to stay current on the
rules, afterall. I don't mean to be snide; if you haven't
noticed this fairly old rule change, what else might you have
missed?

: >equipment or removed from equipment, mismarked, experimental, etc

I think Steve at Down East Microwave (he bought out the non-antenna
part of the company and moved it to NJ--the antenna part is still in
Maine as Directive Systems) has a quantity of the 5.9 to 6.4 GHz
3 watt Avantek GaAs FETs. IM-5964-3s. These are rated at 3 watts,
but people claim to have gotten 4 or even 5+ watts out of them. Usually,
they run them at 12 volts, as opposed to the recommended 9 volts. 12 V
is under the absolute max rating of 14 volts, so it is probably OK
for typical amateur use (non-continuous operation).

They are impedanced matched for 6 cm with low pass networks, so you
can tune them for lower bands. er=10.5 board works great at 2.3 GHz,
you can use little pieces of tuning foil--just like X band. er=2.2
board may require actual capacitors for tuning.

There may also be some surplus dealers in Texas with them as well--from
what I heard thousands were on the surplus market at one time....

>
>

It has been a couple years since I ordered anything from them. They did NOT have a phone, but the address was:

SHF Microwave Parts Co.
7102 W 500 S
La Porte IN 46350

They were very fast with a catalog and very fast with orders, too! And I wasn't satisfied with something I got, and they made it right.

If anyone has bought anything from them lately, let me know. I may get a couple 24 GHz Gunnplexers.

Write to the ARRL! It is an ARRL publication. Subscriptions are $15.00/year in the USA for ARRL members, and $27.00/year for non-ARRL members.

I've been getting it for a few years now and it's worth it. ARRL will also photocopy articles from back issues for a small photocopy fee, if you know what issue the article is in.

>-WaiWong

The cheapest way is to hand-assemble the source on yellow pads of paper.
You can build an EPROM burner with a couple of rows of toggle switches,
a 5V supply, and a 20V supply. Just assert the address you want to program,
assert the data lines, and press a momentary switch to put 20V on the
PROG line. No electronics required other than the power supply stuff.
I did this a lot in the early seventies with the 8035, back when the 8035
was a $200 chip. It is definitely the least expensive development system,
but it is a pain in the neck.

The easiest way is to use the Intel in circuit emulation system... you
can develop in a high level language, drop the emulation pod into your
circuit and run the code, even being able to step through and modify on
the fly. When you have the thing running, you can use the PROM burner
on the ICE box to cut you a PROM that just drops into the circuit. However,
this is very expensive.

Do you want cheapest or do you want easiest?

: Steve Johnson,
: N2FT

There have been several articles in QST and CQ magazine on small
transmitting loops. When properly constructed, they can be very efficient. The
key words are "properly constructed". This requires special components and wel;ding of the
assembly due to circulating currents that are very very high.

One of the loops was used during sweepstakes a year or two ago, and the
author won the 150-watt power category using the loop -- his being in Puerto
Rico
didn't hurt either.

Tom, N5EG

: P.S. Also interested in possibility of using a two or three turn loop. Any takers?

Message-ID: <Pine.HPP.3.91.950428093443.18161A@pmafire.inel.gov>
Source record: 113210

I was reading the Rick Campbell article (QST, 8/92) about direct conversion receivers. In it he mentions that the IF noise output of the mixers may be several dB higher within 10 KHz of DC. Is this correct? If so, would it be reasonable to put a bandpass filter at 25 kHz, and then frequency translate and filter the signal with a DSP?

I don't have a license yet, but I am thinking of what sort of hardware I would like to build.

Howdy!
I'm working on the very same question, having recently received a donation of 20 (used) 800AmpHr 12V Gel Cells for our Search & Rescue mountain-top repeater site. My initial thinking inolves a number of high current 125VAC (coil voltage) relays, a distribution buss, and a fully automatic (complete turn-off) battery charger. Each repeater's power supply would be connected to the battery's buss thru the normally closed contacts of a relay. But the relays are plugged into 125VAC, so the normally open contacts are in use. When the power company goes down, the relays drop out and the battery buss is connected. When AC power returns, the relays energize again, disconnecting the battery buss.

The battery charger detects low battery voltage, so it turns on and brings the batteries back up. These "Fully Automatic - Complete Turn Off" battery chargers are available at places like Walmart.

This is just an idea right now. Would like to hear people's opinions of this plan. Perhaps someone has done this a better way?

Digital Scope.FAQ - Version 1.05

Spring, 1995

Dear Technologist:

This Digital Scope.FAQ file contains many of the answers to the "frequently asked questions" regarding digital scopes.

Key Issues reviewed in this file include:

* DSO INDUSTRY TRENDS (1995)
* PRIMARY DSO FUNCTIONS
* APPLICATIONS
* DISPLAYS
* MEASUREMENTS
* BANDWIDTH & TRIGGER
* DIGITAL SIGNAL PROCESSING <DSP>
* ARCHIVAL & MEMORY
* ADCs
* DEMOS & PURCHASING

Feel free to contact me anytime via Internet (john@wd1v.mv.com) if you have comments, questions, or want the latest version of this file sent to you.

*DSO INDUSTRY TRENDS 1995
More DSOs are now sold than analog scopes. Expect most new scope models to be DSOs and expect them to have faster sampling, higher bandwidths, deeper memories, and lower costs than you might expect. Comparable models have fallen in price by about 50% in the last 4 years. The market is very competitive and that is good news for buyers.

DSOs aren't just for transient capture anymore. Modern DSOs can now process multiple sweeps and generate envelopes, measure statistics of how your signals are varying over time, do simple to complex DSP functions, conduct stand alone tests, archive and print data, even FAX scope screens with measurement and test results to/from remote sites.

DSOs now are the highest BW oscilloscopes available. The highest BW analog scope currently in production is 400 MHz. DSO BW specifications exist > 4 GHz from several manufacturers.

Closeness to sources is also good news for buyers. The vast majority of the DSOs that are sold in the United States are manufactured by US Corporations making delivery, service, and support easier and less expensive.

DSOs are getting more and more computation intensive. Deep memory, multiple channels, large high resolution displays, and enhanced DSP routines tax the

fastest CPUs and smartest firmware. Latest designs use multi-processor architectures.

Upgrade paths for firmware and hardware expansions are becoming more common.

DSOs are now available in 5 different distinctive form factors:

1 PC Card - A to D on a card that uses PC's CPU and memory- PCB Style
Interesting due to low cost. Look out for noise problems from some PC's backplanes.

2 Stand Alone Card - DSO on a card for embedded systems - PCB Style
Interesting due to low cost, small size, fewer noise issues.

3 Handheld - Portable capabilities - Portable Style
Battery operated for field measurements

4 Portable - with some amount of upgrade capabilities - Portable Style
Performance approaching mainframes and low cost due to high competition, high volume, and large scale integrations.

5 Mainframe - typically with plug-ins that determine performance - Lab Style
Highest cost but highest performance and greatest versatility.

REAL TIME SAMPLE RATES (Single Shot) > 10 Giga-samples MEMORY DEPTHS are expanding from 1 K samples to > 8M samples per sweep

DSOs are the primary debugging tools for high speed digital circuits since they can now sample so rapidly and trigger on so many different fault conditions.

Some DSO manufacturers are offering COLOR display options. Higher end versions utilize the colors cleverly with COLOR GRADED PERSISTENCE.

While many applications only require a single channel scope, most users are now purchasing 4 channel DSOs with easy justifications. The additional cost is usually small, they appreciate the "what if I need it" capabilities, and the wider trigger and debugging capabilities to look at > 2 inputs.

Some manufacturers INTERLEAVE the CHANNELS of their DSOs so that, for example, in a 2 channel model, twice the sample rate is achieved when using just 1 channel compared with both channels being used.

Some manufacturers are able to CASCADE the MEMORIES of their DSOs so that, for example, in a 2 channel model, twice the memory depth is achieved when using just 1 channel compared with both channels being used. The benefit is twice the recording time at the maximum sample rate.

Some manufacturers are just now able to both INTERLEAVE the channels AND CASCADE their memories.

DSOs are getting smaller in size, smaller in cost, and larger in functionality. This means that while you might be able to afford more DSOs and they will take up less space, it might take you longer to use them to their full potential. Thus, the user interface is gaining increasing importance. Features need to be extracted as needed quickly without a lot of button pushing, knob twisting,

and frequent trips to the user's manual. What is best for you is what feels most intuitive, easy, and convenient.

DSOs with floppy disk drives are the rule vs. the exception. Almost all new units
offer them - either as options or as standard features.

Most DSO manufacturers offer a number of FREE services:
o Full line catalogs and price sheets
o DSOs for evaluation on your signals with a "how to use it" demonstration
o Application Notes that relate how to take specific measurements or tests
o Seminars to teach basic digital scope technology
o Seminars to teach application specific techniques
o Competitive DSO Comparisons
o Training after delivery for most rapid return on investment
o Toll-free telephone applications assistance to support their platforms
o Drivers for third party software used for remote control and analysis.

*PRIMARY DSO FUNCTIONS
o Archival <Save the waveforms, measurements, tests, etc. to storage media or host>
o Auto-Setup <Sets the instrument up automatically on repetitive waveforms>
o Capture Repetitive Waveforms <Trigger on repetitive waveforms>
o Capture Transient Waveforms <Single shot captures>
o Compute Statistics <Compute variation in waveform(s) measurements>
o Data Transfer <Pass data to/from a host for processing, archival, etc.>
o Find Features <Find where specific data values are (e.g. max.) >
o Make Measurements <Compute values contained in the waveform data>
o Make Tests <Compare predicted results with actual measurements>
o Publications <Print/plot to paper, transparency, disk, etc.>
o Trigger <Detect and trigger on EDGES, WIDTHS, INTERVALS, N# of EVENTS, etc.>
o Trigger Delays <Pre or post precise delays from the trigger>
o View the Data <See the waveforms and visually assess its qualities>
o Waveform Digitizing <Acquiring analog signals and creating digital data>

*APPLICATIONS
Due to expanding primary functions and capabilities, DSOs lend themselves to a wider variety of application areas. Like a computer, the more applications you can use an instrument for, the more valuable it is and the easier it is to justify. Here are a few for you to consider:

o The most obvious one is to use a DSO as an Oscilloscope. Typical applications are electronic circuit design and debug and troubleshooting faulty or intermittent circuits.

o Another common application is as the front end of a Data Acquisition System. DSO's cost per channel has become very competitive. Many people find that the triggering flexibility, deep memory, "live" view of waveforms, and fast transfer rates make the DSO a great candidate. If your experiment is short lived, it is nice to have a scope when you are done vs. a black box that gets shelved and forgotten. Typical applications are research experiments, process

monitoring, and flaw detections.

o DSOs lend themselves to being fully integrated into an ATE System. In this example, the DSO is under remote control from a host computer and conducts its business by computer command. Typical applications are incoming Quality Assurance of components, Manufacturing/Production Functional Test, Final Test, and System Test.

o DSOs can be used (card level or portable rack mounted form factors) and can be embedded into systems that require Analog to Digital conversion and data analysis. Here the DSO is used as a SYSTEM COMPONENT and eliminates the need and time of engineering custom devices.

o DSOs displace/replace many dedicated instruments. You'll see DSOs applied today for all sorts of measurements that used to be taken with specific instruments. Some of them are DMMs, Spectrum Analyzers, Impedance Analyzers, Time Interval Analyzers, Frequency Counters, Counters, Power Meters, etc.

o Some of the common DSO Application fields include:
Aerospace
Automotive Electronics
Avionics
Chemistry
Computer Backplanes/Interfaces
ElectricalComponents
Electric Power
EMP/EMI/EMC
LASERS
Lightning Studies
Magnetic Media <Disks>
MATE
Medical
NDT
Networks/Communications <ATM, FDDI, Ethernet, AX.25,etc.>
Noise/Acoustics
Power Supply Design/Manufacturing
Process Control
RADAR
Semiconductor Design/Manufacturing
SONAR
Telecomm (Switches, Cellular,Telemetry)
Ultrasound Vibration/Mechanical Analysis

*DISPLAYS
Not all DSOs are created equally - especially their displays. The best compact an entire sweep of acquisition memory onto a single screen with a min/max algorithm. The benefit is that you don't have to page thru screens to see the interesting details in your data. Min/max compaction makes faults obvious.

Ideally, the screen will be large enough so that you can see the waveforms AND measurements clearly at the same time. Look out for small diagonal measurement

displays that put measurements on top of the waveform data.

DSO displays are typically specified in terms of resolution and diagonal size. The higher the resolution, the easier it will be to see fine details and the better your publications that have imported DSO screens will appear. The larger the diagonal size, the greater the chance of being able to see critical information on screen all at the same time vs. pages of menus.

Ideally, you should have all the information on screen that you want in your report. Consider things like trigger parameters, ICONS, measurements, input and timebase settings for each trace, sample rate, cursors and their measurements for each trace, clock/calendar. That is a lot of information on screen. How does it look?

Ideally, you should have the ability to EXPAND or ZOOM in on DIFFERENT PARTS of your waveforms to see details more clearly and to limit your measurements to within a given region of data. This means MULTIPLE EXPANSION WINDOWS are best.

Ideally, the graticule <grid> should be done in software and allow multiple traces to be displayed, each within their own grid. This preserves the full scale voltage input ranges for best accuracy.

Ideally, the DSO display should have a report of what the front panel status is so that the entire setup of the front panel can be observed, verified, and potentially printed.

*MEASUREMENTS
No more fingerprints on the screen from counting grid squares! Modern scopes display precise measurements of any waveform you capture. The "classic" scope measurements are either made with cursors or automatically in a modern DSO.

ABSOLUTE AMPLITUDE at a given point

ABSOLUTE TIME <from trigger> at a given point

RELATIVE AMPLITUDE <difference in amplitude between any 2 points>

RELATIVE TIME <difference in time between any 2 points>

Ideally, EACH TRACE should have its own set of cursors for SIMULTANEOUS measurements on all displayed traces.

You should be able to make measurements automatically on all displayed traces.

Pay close attention to the DSO's ability to detect and measure signals that are changing. This is often overlooked and yet it is often the most needed capability.

Ideally, the measurements should include STATISTICS so you can see and measure how much your waveforms are changing with every new trigger.

*BANDWIDTH & TRIGGER
Bandwidth – BW is the amount your signal will be attenuated by the DSOs front end amplifier - specified at the -3dB point - as a function of input frequency. Remember that BW ratings are at the input to the amplifier and that your PROBES

might also attenuate your signals.

Remember that -3dB is down in amplitude by almost 30%. You probably don't want a 30% error in your amplitude measurements. Consider the higher BW DSOs practical so your measurements are back up the BW response curve where you can be certain of accurate measurements.

Look out for DSOs that have BW ratings that reflect their best performance but only in certain voltage ranges. Make sure the actual rating matches your real requirement.

Look out for DSOs that reduce sample rates by the number of channels activated. This could cause aliasing by changing the relationship of how fast the DSO is sampling vs. the BW of the signals you are digitizing. Most DSOs today report the sample rate on screen. Pay attention to it as you change the number of active channels and/or sweep speed settings.

Many scopes have analog BW specifications far greater than their single-shot sample rates nyquist (.5 sample rate) frequency. This is so when repetitive waveforms are viewed, the maximum BW signals can be seen. BE CERTAIN YOU CAN SAMPLE FAST ENOUGH IN REAL TIME (SINGLE SHOT) MODE ON ALL CHANNELS SO AS NOT TO ALIAS!

TRIGGER
If you can't TRIGGER on the waveforms you need to see, you have a real problem! This should be center stage for your demo if you are looking at a new scope. There are various trigger capabilities and a combination of them that are easy to use that capture your waveforms is the most desirable.

Know how frequently you need to trigger. The maximum trigger rate is a key specification that isn't often published in manufacturer's specifications as there can be many variables. Evaluate and compare!

Some DSOs have a MEMORY SEGMENTATION feature that lets you trigger very rapidly and fill just a portion (1 segment out of n number of segments) per trigger.

Most DSOs will let you trigger on the width of pulses <GLITCH>, the INTERVALS between pulses, the LOGICAL or PATTERN conditions between inputs, after specific delays by events or time, drop out conditions, etc. Compare!

Look for TRIGGER ICONS that relate how the current trigger selection is working. This is very helpful if you are looking at a screen dump later and trying to reacquire with the same trigger conditions.

DSOs are valuable tools for looking at video signals but not all DSOs offer a video trigger as a standard feature. Compare!

DSOs can almost always capture single shot events but not always with the amount of pre or post trigger delay you might need. If your application requires capturing a lot of transient waveforms, look into the span of trigger delay as an important spec.

*DIGITAL SIGNAL PROCESSING <DSP>
By doing math on the waveforms, additional information can be obtained. Some

instruments really slow down when DSP is being performed. Ask for benchmark specifications on the key functions you need. Don't waste your time looking at DSOs that just aren't fast enough.

Another DSP concern is that you may wish to do a SERIES of functions. How many functions can be chained varies from model to model. Compare!

Consider these potential DSP functions:

Arithmetic (Add, Subtract, Multiply, Divide any traces)
Averaging (Get rid of random noise, improve resolution)
Enhanced Resolution (Smoothing, improves resolution at reduced BW)
Functions (Integrate, Differentiate, Envelope, etc.)
FFT (Spectral analysis of any trace)
Histograms (Distributions of measured values)
Pass/Fail Testing (Comparisons of live waveforms to masks or measurements)
Trending (Time series of measured values)

*ARCHIVAL & MEMORY
ARCHIVAL
Floppy Disks - They are nice - should be MS-DOS and should come with file formatter so you can convert to ASCII and back then back to binary. Macintosh can read MS-DOS disks so both popular platforms can be used. Make sure you can print to disk so that you can import the scope screens into your documentation.

Hard Disks - They are becoming available and offer the same kind of convenience that is realized in PCs.

Memory Cards - They are expensive but they are fast - up to 200 times faster than a floppy. Require reader at PC to use the data.

Printers/Plotters - They are the best way of showing the world your waveforms and your measurements. Plotters are great for elegant color - most impressive for overheads.

ARCHIVAL DATA FILE TYPES:
Waveform files - Binary but with conversions to ASCII for import into other programs and from ASCII to scope's binary format.

Set Up Files - Most scopes have front panel setups that you can recall and store either in nonvolatile memory in scope or to disk.

Screen Plots - "Print to disk" graphics files that are screen dump imports into your word processor.

MEMORY
Tricky! Manufactures specify their largest numbers. Look out for some DSO's acquisition memory values that divide by the number of active channels.

The acquisition memory depth on any channel x the sample rate maximum recording time at the maximum sample rate. Turning the time per division control towards longer acquisition times will slow the sample rate and change the banner specification of the DSO. This is why deep memory can be so important. Know what you need for maximum sample rate recording time and keep

a sharp eye on the sample rate as you use the instrument.

Don't confuse acquisition memory with reference memory specifications. Reference memory is used for copies of waveforms recorded earlier and made available for comparison either by viewing or by mathematics. Some scopes have longer acquisition memories than storage memory. Compare!

Not all DSOs have the same number of reference memories. More are better. Make sure they have the width to contain your processed data. You can't store 12 bit averaged waveform data in 8 bit reference memory. Compare.

Not all DSOs have the same number of memories for front panel set-up/storage and recall. Compare.

Some manufacturers offer MEMORY CARDS for additional reference memory.

Some scopes allow for MEMORY SEGMENTATION where you can acquire multiple trigger events in a single sweep display. A few models will also record the time of each trigger event that occurred.

*ADCs
ADCs - SPEED:
This is tricky. Manufactures specify their fastest ADC numbers. Lookout for SAMPLE RATE banner spec. values that divide by the number of channels that are turned on. Look out also for short record length DSOs that can only sample at maximum rates for short periods of time. Ideally, the sample rate value should be seen on screen all the time.

Check to make certain what the SAMPLE RATE speeds relate to - either REAL TIME <Single Shot> or RIS <Random Interleaved Sampling (same as EQUIVALENT TIME) rates.

REAL TIME is used for transient capture and should be > 2 times your highest frequency observed. Random Interleaved Sampling <RIS> or EQUIVALENT TIME <ET> is used for repetitive waveforms.

ADCS - RESOLUTION:
This refers to full scale resolution. An 8 bit digitizer will divide full scale input voltages by 255 counts. Thus the minimum discernible sampled value on a 1 volt full scale 8 bit scope would be 1 / 256 .00390 volts.

Some DSOs display amplitude and timing values along the interpretive line that connects the samples. This increases the resolution of your measurements and potentially the accuracy.

If you have repetitive waveforms, you can increase your vertical resolution with AVERAGING.

If you have transient waveforms, you can increase your vertical resolution by low-pass filtering each sweep <FIR> for ENHANCED RESOLUTION.

ADCS - ACCURACY:
Not all ADCs are created equally. The most common figure of merit is EFFECTIVE BITS that basically relate the number of correct bits of a given ADC's actual

measurements vs.ideal.

*DEMOS & PURCHASING
You can contact these manufacturers directly. They will send you their full-line catalog and application notes that pertain to DSOs and current pricing. ☐
The primary American manufacturers of DSOs are:

o Hewlett-Packard 800 452-4844 in Palo Alto, CA

o LeCroy Corporation 800 553-2769 in Chestnut Ridge, NY

o Tektronix Corporation 800 426-2200 in Beaverton, OR

If you live outside of the United States, you should contact each manufacturer's local sales office in your area. ☐

BEFORE THE DEMO:
Be in touch with your business needs as they relate to your DSO needs. Are you going to faster designs soon that might impact the banner specs you'll need? Is this DSO the tool for that design or some problem you have now? Future requirements might impact how long "the perfect scope" looks perfect. Will the DSO effect your ability to finish a project on time? Costs to own vs. costs to wait are good values to calculate and put in your justification. Plan right for the future.

Let your S I G N A L S determine the primary specifications of the instrument you choose.

Let your A P P L I C A T I O N determine your secondary specifications.

Make your "Wish List". Write down exactly what you expect the target DSO to do. Try to find out what the most popular DSO is for your application. Talk to some people that use it and find out what they like/dislike. See if they would buy the same model again.

Get a sense of how solid your budget is and how soon you can place an order once you make a decision. If it is more than 6 months away and your short term needs are critical, consider rental or lease.

Plan several different demos with different manufacturers. Let them know it is a "competitive situation" and you want the best DSO you can get that meets your needs. Relate that you expect to place an order within a week after all the evaluations are completed. You'll get a lot of attention and the best of services.

Schedule the demos in your lab instead of your conference room. You'll be closer to your signals and the real environment <what noise?> where the DSO will have to work. If more than one (1) person is to use the DSO, make sure the demo occurs when everyone can see it. If your group is scattered and tough to catch, try EMAIL or a poster by the coffee pot. That will shorten everyone's learning curve and produce the best questions.

You should plan to see a demo of the exact model DSO you are thinking of using - with all the options you believe you'll need - conducted by a Sales Engineer that knows the instrument and what you need it to do extremely well. Some manufacturers use distributors or reps that won't know DSO technology or applications very well. It is usually best if you can get a factory's Sales Engineer to conduct your demo and review your application.

The DSO Manufacturer's Sales Engineer should be a GREAT RESOURCE to you. By reviewing your application and assisting you with a model selection that is technically correct, your demo will be much less likely to disappoint you or anyone else.

If you have never met the Sales Engineer, plan to start with a quick tour of your facility and dove tail into why you need the DSO showing him the area that it will be used in and what you expect it to do. The Sales Engineer's tour may let him see things that will help you that you hadn't thought about.

DURING THE DEMO:
A quick overview of the DSO's banner specifications and key features is a good place to start the demo. Focus quickly on how to drive the front panel and how to extract the various functions. If it looks complex, save front panels you'll need to recall. Ask questions.

You should see your signals on screen EARLY into the demo and plan to borrow the DSO for at least a few days to evaluate it if the demo goes well.

The demo should prove that the DSO model being demoed can do your specific application(s). If the demo can't do that, you are probably wasting time by evaluating it further AFTER the demo. If the DSO has to do a specific task, see it happen at the demo and learn how to replicate the settings so you can do it after the Sales Engineer leaves. If the DSO is for general purpose use, see it doing the most difficult task you can imagine before the Sales Engineer leaves.

Pay attention to the NUMBER OF BUTTONS that have to get pushed to go from one operation to the next. If the demo is really canned, force some hopping around so you see typical vs. streamlined operation. Remember, you are supposed to do this AND engineer something. If it takes major brain power just to drive the scope, be cautious.

If this is your first demo, ask why this DSO model is a superior choice for you. Build a list of advantages that allow you to compare and make a good choice. Add these items to your Wish List of what you expect the DSO to do.

Find out how long the DSO model you are looking at has been on the market. Ask for MTBF figures <Mean Time Between Failures>. Find out where the closest service center is and how long a typical repair or calibration turnaround might take. See what their policy is for loaner units should emergency service be required.

If you are a LARGE company, find out who else in your company is using the same/similar DSO from the Sales Engineer. Chat with the other users and get their opinions after the demo but during the evaluation. They might be a good source for overcoming common measurement problems that you will have as well as a potential source for remote control software.

If you are a SMALL company, find out who else in your industry within your area is using the same/similar DSO from the Sales Engineer. Call them and get their opinions after the demo during your evaluation.

Take as much time as you like. Don't rush it. Ask questions. Record answers. Enjoy the process. If you get saturated, take a break and return.

Check the demo DSO that will be left for evaluation to make sure:
o That it will accept your full scale voltages
o That it samples fast enough to capture your waveforms with high fidelity
o That it is not affected by other signals in your environment
o That it has the options necessary to take your measurements
o That it has a manual covering operations o That you have the applications engineering telephone number for support during your evaluation period

DURING THE EVALUATION:
Make notes of the questions you have and record the answers. It will keep you focused.

Call the factory's application's group and test them to see how well they answer your questions. Get application notes sent to you that address your areas of interest and see how soon they arrive. Is there ever a telephone or service charge for contacting them?

Don't believe there is one DSO that does EVERYTHING. Most labs have a variety of scopes for various functions. Don't be discouraged if the model you are looking at doesn't do EVERYTHING. But don't accept a model that doesn't do what you need.

Try this experiment with the DSO you are considering. Connect a signal source up to the DSO where you can vary the amplitude of the signal by very small amounts. The waveform should have at least 3 or 4 complete cycles on screen and be 90% of full scale. Once you have a stable trigger, store a copy of the waveform into a reference memory. Then activate math so that all new waveforms are being subtracted from the waveform in reference memory. See how little you can change the amplitude level on the generator to see and measure the difference with the scope. Remember: A large part of the utility of a scope is verifying that things are exactly as they should be and seeing when they aren't.

AFTER THE EVALUATION:
If the DSO met your expectations perfectly and you have decided to purchase it, you might try to see if you can keep the evaluation unit until your new unit arrives.

If the DSO met your expectations and you have decided to keep evaluating, make sure you know what your likes/dislikes are for comparing with the next unit. Many people make a chart for grading and comparison. The more units you look at, the greater the chance for confusion and frustration. Stay focused on what you need!

If the DSO didn't meet your expectations, make sure you know why and include the new things you've discovered in your Wish List that you've learned.

PURCHASING
Get a list of ALL OPTIONS available for the DSO so that you can order the exact configuration that really addresses your needs. Make sure you and your Sales Engineer determine issues that might include:
o Memory Expansion Options
o Waveform Processing Options
o Disk Drive Options
o Printer Options
o Hardware Options <External clock, video trigger, I/O, iso amps, etc.>
o Active Probes
o Probes with different attenuations than those supplied with the DSO
o Scope Cart
o Rack Mount
o Hard Shell Transit Case for safe and convenient shipping your DSO to remote sites
o Probes for all channels <Not all DSOs come with a probe/channel!>

You should also explore the manufacturer's policies and costs regarding:
o Applications Assistance
o Calibrations- NIST, MIL, Performance Checks, At-Site Service
o Capabilities for Training Users
o DSO System Software/Firmware Upgrades
o Warranty Period - Extensions

You should get a written quotation that relates the model, specifications, options, all costs, delivery, and any discounts available. Most manufacturers offer Educational, GSA, Quantity, and Demo discounts if you qualify.

You might also consider rental or leasing options. Some rental companies offer equity rentals where rental/lease fees apply towards purchase.

73 Magazine had a "NASA BEEP" ckt in the late 70s that gave a beep when the
mike PTT was first activated and after the PTT was released. I don't
remember much about the ckt (I did build one), but it used a 555 as the tone
generator, and "regenerated" the PTT signal to add the required delay
after PTT release during the Beep. I might still have the article
somewhere if you can't find it. I seem to also recall that the giant ckt books have a ckt like this
as another reference source.

: As far as I can see, the circuit is basically a 94MHz LO, a
: mixer, appropriate filters and the necessary switching...

: If I redesign the filters for the appropriate frequencies, is there
: much else I need to do to make it work 'the other way round' ?

Unfortunately, its not quite reciprocol, if you work out where the
spurious products end up. For instance, the 3rd harmonic of the
source is around 150 MHz, not all that far from 144 MHz. In the
USA, 60 dB of spurious rejection is needed for a 25 watt transmitter.
Perhaps more if it falls on a popular frequency :-(. This isn't
trivial for most people. However, if you only needed 30 dB of
spurious rejection, the filtering wouldn't be that difficult.

>
>James M. Potter, President Internet: jpawi@roadrunner.com

A correction to the above:

For no coupling at all, Zoo (that is, the differential mode
impedance) is infinity, not Zo. You are correct that Zoe would be the
same as Zo.

As far as broadband couplers being an art, I would disagree and
claim that E.G. Cristal and his associates pretty much made this
into a science 30 years ago (see IEEE trans. MTT of that era).
Since then, others have extrapolated his work from stepped
couplers to tapered couplers. The thing that is difficult about
these devices is making them manufacturable. You can always
build a single prototype and get excellent results.
I would concede that there is some artfulness in getting maximum
directivity. This is mainly of function of keeping everything as
a TEM wave of constant velocity inside the coupler. Avoid
dielectrics as much as possible, or fill the whole inside with a
uniform dielectric. Don't try to use a non-TEM transmission line
like microstrip and expect to get 45 dB. directivity. For ham
work, SSS construction is probably your best bet if you don't
have a Bridgeport mill in your garage.

Source record: 113221

I hope this is the correct group to put this question. I'm not sure if anyone can help but I an trying to find out whether it was at all possible to convert these walkie-talkies to the 70cm band. I brought a MX 360 out of curiosity. It is the UHF model but I can't tell if it is high or low band. I think that this particular one was designed for some special use. The guy who sold it seemed to have a lot of them going for dirt cheap and said that the conversion was possible with little difficulty. Though I must say he has lead me on a bit. When I tried to get any specifics from him he tried to avoid a direct answer. Any help or info would be really appreciated. PLS. email

Thanks,
Ronald Newell (N2YSV)

1683. Intermod filters for 2m

Hi! I love my Kenwood 251-A, except for the fact that local pagers in my area wipe out some frequencies, and make some fairly local repeaters unusable. Can I get some sort of filter to get rid of some of this intermod? I don't need to get rid of it all, just cut it down significantly to let the repeaters through on a couple frequencies.

Thanks,
73
Chris.

... ARRRRRGGGHHH!!!! ... Tension breaker, had to be done.

Aside from redesigning the filters, you will need to replace the 6 meter preamplifier for RX and power amp stage for TX with respective 2 meter stages.
The core of the transverter is L.O. and the mixer which can remain the same. On TX, the lo power 6 meter signal will get mixed with the L.O. and the filter on the output of the mixer will need to pass the sum (2 meter signal) then get amplified.
